however this code path is not maintained by the D-Bus developers and
if it breaks you get to keep the pieces.  If you have selected this
option in err please reconfigure with expat (e.g. --with-xml=expat)."

```

This removes parts of the standard D-Bus API and ABI (the 't' and 'x'

typecodes, the dbus_int64_t and dbus_uint64_t types, etc.) and should only be

used if your compiler lacks support for 64-bit integers. Please report a bug

with details of your platform and compiler.

This option is likely to be removed in future, unless the D-Bus developers

receive reports that it is still needed.

The D-Bus glib bindings are licensed to you under your choice of the Academic Free License version 2.1, or the GNU General Public License version 2. Both licenses are included here. Some of the standalone binaries are under the GPL only; in particular, but not limited to, tests/decode-gcov.c. Each source code file is marked with the proper copyright information.

The Academic Free License
v. 2.1

This Academic Free License (the "License") applies to any original work of authorship (the "Original Work") whose owner (the "Licensor") has placed the following notice immediately following the copyright notice for the Original Work:

Licensed under the Academic Free License version 2.1

1) Grant of Copyright License. Licensor hereby grants You a world-wide, royalty-free, non-exclusive, perpetual, sublicenseable license to do the following:

a) to reproduce the Original Work in copies;

- b) to prepare derivative works ("Derivative Works") based upon the Original Work;
- c) to distribute copies of the Original Work and Derivative Works to the public;
- d) to perform the Original Work publicly; and
- e) to display the Original Work publicly.

2) Grant of Patent License. Licensor hereby grants You a world-wide, royalty-free, non-exclusive, perpetual, sublicenseable license, under patent claims owned or controlled by the Licensor that are embodied in the Original Work as furnished by the Licensor, to make, use, sell and offer for sale the Original Work and Derivative Works.

3) Grant of Source Code License. The term "Source Code" means the preferred form of the Original Work for making modifications to it and all available documentation describing how to modify the Original Work. Licensor hereby agrees to provide a machine-readable copy of the Source Code of the Original Work along with each copy of the Original Work that Licensor distributes. Licensor reserves the right to satisfy this obligation by placing a machine-readable copy of the Source Code in an information repository reasonably calculated to permit inexpensive and convenient access by You for as long as Licensor continues to distribute the Original Work, and by publishing the address of that information repository in a notice immediately following the copyright notice that applies to the Original Work.

4) Exclusions From License Grant. Neither the names of Licensor, nor the names of any contributors to the Original Work, nor any of their trademarks or service marks, may be used to endorse or promote products derived from this Original Work without express prior written permission of the Licensor. Nothing in this License shall be deemed to grant any rights to trademarks, copyrights, patents, trade secrets or any other intellectual property of Licensor except as expressly stated herein. No patent license is granted to make, use, sell or offer to sell embodiments of any patent claims other than the licensed claims defined in Section 2. No right is granted to the trademarks of Licensor even if such marks are included in the Original Work. Nothing in this License shall be interpreted to prohibit Licensor from licensing under different terms from this License any Original Work that Licensor otherwise would have a right to license.

5) This section intentionally omitted.

6) Attribution Rights. You must retain, in the Source Code of any Derivative Works that You create, all copyright, patent or trademark notices from the Source Code of the Original Work, as well as any notices of licensing and any descriptive text identified therein as an "Attribution Notice." You must cause the Source Code for any Derivative Works that You create to carry a prominent Attribution

Notice reasonably calculated to inform recipients that You have modified the Original Work.

7) Warranty of Provenance and Disclaimer of Warranty. Licensor warrants that the copyright in and to the Original Work and the patent rights granted herein by Licensor are owned by the Licensor or are sublicensed to You under the terms of this License with the permission of the contributor(s) of those copyrights and patent rights. Except as expressly stated in the immediately preceding sentence, the Original Work is provided under this License on an "AS IS" BASIS and WITHOUT WARRANTY, either express or implied, including, without limitation, the warranties of NON-INFRINGEMENT, MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY OF THE ORIGINAL WORK IS WITH YOU. This DISCLAIMER OF WARRANTY constitutes an essential part of this License. No license to Original Work is granted hereunder except under this disclaimer.

8) Limitation of Liability. Under no circumstances and under no legal theory, whether in tort (including negligence), contract, or otherwise, shall the Licensor be liable to any person for any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or the use of the Original Work including, without limitation, damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses. This limitation of liability shall not apply to liability for death or personal injury resulting from Licensor's negligence to the extent applicable law prohibits such limitation. Some jurisdictions do not allow the exclusion or limitation of incidental or consequential damages, so this exclusion and limitation may not apply to You.

9) Acceptance and Termination. If You distribute copies of the Original Work or a Derivative Work, You must make a reasonable effort under the circumstances to obtain the express assent of recipients to the terms of this License. Nothing else but this License (or another written agreement between Licensor and You) grants You permission to create Derivative Works based upon the Original Work or to exercise any of the rights granted in Section 1 herein, and any attempt to do so except under the terms of this License (or another written agreement between Licensor and You) is expressly prohibited by U.S. copyright law, the equivalent laws of other countries, and by international treaty. Therefore, by exercising any of the rights granted to You in Section 1 herein, You indicate Your acceptance of this License and all of its terms and conditions.

10) Termination for Patent Action. This License shall terminate automatically and You may no longer exercise any of the rights granted to You by this License as of the date You commence an action, including a cross-claim or counterclaim, against Licensor or any licensee alleging that the Original Work infringes a patent. This termination provision shall not apply for an action alleging patent infringement by combinations of the Original Work with other software

or hardware.

11) Jurisdiction, Venue and Governing Law. Any action or suit relating to this License may be brought only in the courts of a jurisdiction wherein the Licensor resides or in which Licensor conducts its primary business, and under the laws of that jurisdiction excluding its conflict-of-law provisions. The application of the United Nations Convention on Contracts for the International Sale of Goods is expressly excluded. Any use of the Original Work outside the scope of this License or after its termination shall be subject to the requirements and penalties of the U.S. Copyright Act, 17 U.S.C. 101

et seq., the equivalent laws of other countries, and international treaty. This section shall survive the termination of this License.

12) Attorneys Fees. In any action to enforce the terms of this License or seeking damages relating thereto, the prevailing party shall be entitled to recover its costs and expenses, including, without limitation, reasonable attorneys' fees and costs incurred in connection with such action, including any appeal of such action. This section shall survive the termination of this License.

13) Miscellaneous. This License represents the complete agreement concerning the subject matter hereof. If any provision of this License is held to be unenforceable, such provision shall be reformed only to the extent necessary to make it enforceable.

14) Definition of "You" in This License. "You" throughout this License, whether in upper or lower case, means an individual or a legal entity exercising rights under, and complying with all of the terms of, this License. For legal entities, "You" includes any entity that controls, is controlled by, or is under common control with you. For purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

15) Right to Use. You may use the Original Work in all ways not otherwise restricted or conditioned by this License or by law, and Licensor promises not to interfere with or be responsible for such uses by You.

This license is Copyright (C) 2003-2004 Lawrence E. Rosen. All rights reserved. Permission is hereby granted to copy and distribute this license without modification. This license may not be modified without the express written permission of its copyright owner.

--

END OF ACADEMIC FREE LICENSE. The following is intended to describe the essential

differences between the Academic Free License (AFL) version 1.0 and other open source licenses:

The Academic Free License is similar to the BSD, MIT, UoI/NCSA and Apache licenses in many respects but it is intended to solve a few problems with those licenses.

* The AFL is written so as to make it clear what software is being licensed (by the inclusion of a statement following the copyright notice in the software). This way, the license functions better than a template license. The BSD, MIT and UoI/NCSA licenses apply to unidentified software.

* The AFL contains a complete copyright grant to the software. The BSD and Apache licenses are vague and incomplete in that respect.

* The AFL contains a complete patent grant to the software. The BSD, MIT, UoI/NCSA and Apache licenses rely on an implied patent license and contain no explicit patent grant.

* The AFL makes it clear that no trademark rights are granted to the licensor's trademarks. The Apache license contains such a provision, but the BSD, MIT and UoI/NCSA licenses do not.

* The AFL includes the warranty by the licensor that it either owns the copyright or that it is distributing the software under a license. None of the other licenses contain that warranty. All other warranties are disclaimed, as is the case for the other licenses.

* The AFL is itself copyrighted (with the right granted to copy and distribute without modification). This ensures that the owner of the copyright to the license will control changes. The Apache license contains a copyright notice, but the BSD, MIT and UoI/NCSA licenses do not.

GNU GENERAL PUBLIC LICENSE

Version 2, June 1991

Copyright (C) 1989, 1991 Free Software Foundation, Inc.
51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA

Everyone is permitted to copy and distribute verbatim copies
of this license document, but changing it is not allowed.

Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Library General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original

authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

GNU GENERAL PUBLIC LICENSE
TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

a) You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.

b) You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

c) If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this

License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

a) Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

b) Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

c) Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component

itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

5. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.

6. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.

7. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot

impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

8. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

9. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

NO WARRANTY

11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS

TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

END OF TERMS AND CONDITIONS

How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

<one line to give the program's name and a brief idea of what it does.>

Copyright (C) <year> <name of author>

This program is free software; you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; either version 2 of the License, or (at your option) any later version.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program; if not, write to the Free Software Foundation, Inc., 51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

```
Gnomovision version 69, Copyright (C) year name of author
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type
`show w'.
```

```
This is free software, and you are welcome to redistribute it
under certain conditions; type `show c' for details.
```

The hypothetical commands `show w' and `show c' should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than `show w' and `show c'; they could even be

mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the program, if necessary. Here is a sample; alter the names:

Yoyodyne, Inc., hereby disclaims all copyright interest in the program
'Gnomovision' (which makes passes at compilers) written by James Hacker.

<signature of Ty Coon>, 1 April 1989
Ty Coon, President of Vice

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Library General Public License instead of this License.

File = COPYING.~1~

D-Bus is licensed to you under your choice of the Academic Free License version 2.1, or the GNU General Public License version 2 (or, at your option any later version).

Both licenses are included here. Some of the standalone binaries are under the GPL only; in particular, but not limited to, tools/dbus-cleanup-sockets.c and test/decode-gcov.c. Each source code file is marked with the proper copyright information - if you find a file that isn't marked please bring it to our attention.

The Academic Free License
v. 2.1

This Academic Free License (the "License") applies to any original work of authorship (the "Original Work") whose owner (the "Licensor") has placed the following notice immediately following the copyright notice for the Original Work:

Licensed under the Academic Free License version 2.1

1) Grant of Copyright License. Licensor hereby grants You a world-wide, royalty-free, non-exclusive, perpetual, sublicenseable license to do the following:

- a) to reproduce the Original Work in copies;
- b) to prepare derivative works ("Derivative Works") based upon the Original Work;
- c) to distribute copies of the Original Work and Derivative Works to the public;
- d) to perform the Original Work publicly; and
- e) to display the Original Work publicly.

2) Grant of Patent License. Licensor hereby grants You a world-wide, royalty-free, non-exclusive, perpetual, sublicenseable license, under patent claims owned or controlled by the Licensor that are embodied in the Original Work as furnished by the Licensor, to make, use, sell and offer for sale the Original Work and Derivative Works.

3) Grant of Source Code License. The term "Source Code" means the preferred form of the Original Work for making modifications to it and all available documentation describing how to modify the Original Work. Licensor hereby agrees to provide a machine-readable copy of the Source Code of the Original Work along with each copy of the Original Work that Licensor distributes. Licensor reserves the right to satisfy this obligation by placing a machine-readable copy of the Source Code in an information repository reasonably calculated to permit inexpensive and convenient access by You for as long as Licensor continues to distribute the Original Work, and by publishing the address of that information repository in a notice immediately following the copyright notice that applies to the Original Work.

4) Exclusions From License Grant. Neither the names of Licensor, nor the names of any contributors to the Original Work, nor any of their trademarks or service marks, may be used to endorse or promote products derived from this Original Work without express prior written permission of the Licensor. Nothing in this License shall be deemed to grant any rights to trademarks, copyrights, patents, trade secrets or any other intellectual property of Licensor except as expressly stated herein. No patent license is granted to make, use, sell or offer to sell embodiments of any patent claims other than the licensed claims defined in Section 2. No right is granted to the trademarks of Licensor even if such marks are included in the Original Work. Nothing in this License shall be interpreted to prohibit Licensor from licensing under different terms from this License any Original Work that Licensor otherwise would have a right to license.

5) This section intentionally omitted.

6) Attribution Rights. You must retain, in the Source Code of any Derivative Works that You create, all copyright, patent or trademark notices from the Source Code of the Original Work, as well as any notices of licensing and any descriptive text identified therein as an

"Attribution Notice." You must cause the Source Code for any Derivative Works that You create to carry a prominent Attribution Notice reasonably calculated to inform recipients that You have modified the Original Work.

7) Warranty of Provenance and Disclaimer of Warranty. Licensor warrants that the copyright in and to the Original Work and the patent rights granted herein by Licensor are owned by the Licensor or are sublicensed to You under the terms of this License with the permission of the contributor(s) of those copyrights and patent rights. Except as expressly stated in the immediately preceding sentence, the Original Work is provided under this License on an "AS IS" BASIS and WITHOUT WARRANTY, either express or implied, including, without limitation, the warranties of NON-INFRINGEMENT, MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY OF THE ORIGINAL WORK IS WITH YOU. This DISCLAIMER OF WARRANTY constitutes an essential part of this License. No license to Original Work is granted hereunder except under this disclaimer.

8) Limitation of Liability. Under no circumstances and under no legal theory, whether in tort (including negligence), contract, or otherwise, shall the Licensor be liable to any person for any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or the use of the Original Work including, without limitation, damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses. This limitation of liability shall not apply to liability for death or personal injury resulting from Licensor's negligence to the extent applicable law prohibits such limitation. Some jurisdictions do not allow the exclusion or limitation of incidental or consequential damages, so this exclusion and limitation may not apply to You.

9) Acceptance and Termination. If You distribute copies of the Original Work or a Derivative Work, You must make a reasonable effort under the circumstances to obtain the express assent of recipients to the terms of this License. Nothing else but this License (or another written agreement between Licensor and You) grants You permission to create Derivative Works based upon the Original Work or to exercise any of the rights granted in Section 1 herein, and any attempt to do so except under the terms of this License (or another written agreement between Licensor and You) is expressly prohibited by U.S. copyright law, the equivalent laws of other countries, and by international treaty. Therefore, by exercising any of the rights granted to You in Section 1 herein, You indicate Your acceptance of this License and all of its terms and conditions.

10) Termination for Patent Action. This License shall terminate automatically and You may no longer exercise any of the rights granted to You by this License as of the date You commence an action, including a cross-claim or counterclaim, against Licensor or any licensee alleging that the Original Work infringes a patent. This

termination provision shall not apply for an action alleging patent infringement by combinations of the Original Work with other software or hardware.

11) Jurisdiction, Venue and Governing Law. Any action or suit relating to this License may be brought only in the courts of a jurisdiction wherein the Licensor resides or in which Licensor conducts its primary business, and under the laws of that jurisdiction excluding its conflict-of-law provisions. The application of the United Nations Convention on Contracts for the International Sale of Goods is expressly excluded. Any use of the Original Work outside the scope of this License or after its termination shall be subject to the requirements and penalties of the U.S. Copyright Act, 17 U.S.C. Æ,Â§ 101 et seq., the equivalent laws of other countries, and international treaty. This section shall survive the termination of this License.

12) Attorneys Fees. In any action to enforce the terms of this License or seeking damages relating thereto, the prevailing party shall be entitled to recover its costs and expenses, including, without limitation, reasonable attorneys' fees and costs incurred in connection with such action, including any appeal of such action. This section shall survive the termination of this License.

13) Miscellaneous. This License represents the complete agreement concerning the subject matter hereof. If any provision of this License is held to be unenforceable, such provision shall be reformed only to the extent necessary to make it enforceable.

14) Definition of "You" in This License. "You" throughout this License, whether in upper or lower case, means an individual or a legal entity exercising rights under, and complying with all of the terms of, this License. For legal entities, "You" includes any entity that controls, is controlled by, or is under common control with you. For purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

15) Right to Use. You may use the Original Work in all ways not otherwise restricted or conditioned by this License or by law, and Licensor promises not to interfere with or be responsible for such uses by You.

This license is Copyright (C) 2003-2004 Lawrence E. Rosen. All rights reserved. Permission is hereby granted to copy and distribute this license without modification. This license may not be modified without the express written permission of its copyright owner.

END OF ACADEMIC FREE LICENSE. The following is intended to describe the essential differences between the Academic Free License (AFL) version 1.0 and other open source licenses:

The Academic Free License is similar to the BSD, MIT, UoI/NCSA and Apache licenses in many respects but it is intended to solve a few problems with those licenses.

* The AFL is written so as to make it clear what software is being licensed (by the inclusion of a statement following the copyright notice in the software). This way, the license functions better than a template license. The BSD, MIT and UoI/NCSA licenses apply to unidentified software.

* The AFL contains a complete copyright grant to the software. The BSD and Apache licenses are vague and incomplete in that respect.

* The AFL contains a complete patent grant to the software. The BSD, MIT, UoI/NCSA and Apache licenses rely on an implied patent license and contain no explicit patent grant.

* The AFL makes it clear that no trademark rights are granted to the licensor's trademarks. The Apache license contains such a provision, but the BSD, MIT and UoI/NCSA licenses do not.

* The AFL includes the warranty by the licensor that it either owns the copyright or that it is distributing the software under a license. None of the other licenses contain that warranty. All other warranties are disclaimed, as is the case for the other licenses.

* The AFL is itself copyrighted (with the right granted to copy and distribute without modification). This ensures that the owner of the copyright to the license will control changes. The Apache license contains a copyright notice, but the BSD, MIT and UoI/NCSA licenses do not.

GNU GENERAL PUBLIC LICENSE
Version 2, June 1991

Copyright (C) 1989, 1991 Free Software Foundation, Inc.
51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA

Everyone is permitted to copy and distribute verbatim copies
of this license document, but changing it is not allowed.

Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Library General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so

that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

GNU GENERAL PUBLIC LICENSE
TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

a) You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.

b) You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

c) If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this

License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

a) Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

b) Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

c) Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component

itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

5. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.

6. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.

7. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot

impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

8. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

9. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

NO WARRANTY

11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS

TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

END OF TERMS AND CONDITIONS

How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

<one line to give the program's name and a brief idea of what it does.>

Copyright (C) <year> <name of author>

This program is free software; you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; either version 2 of the License, or (at your option) any later version.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program; if not, write to the Free Software Foundation, Inc., 51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

```
Gnomovision version 69, Copyright (C) year name of author
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type
`show w'.
```

```
This is free software, and you are welcome to redistribute it
under certain conditions; type `show c' for details.
```

The hypothetical commands `show w' and `show c' should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than `show w' and `show c'; they could even be

mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the program, if necessary. Here is a sample; alter the names:

```
Yoyodyne, Inc., hereby disclaims all copyright interest in the
program
`Gnomovision' (which makes passes at compilers) written by James
Hacker.
```

```
<signature of Ty Coon>, 1 April 1989
Ty Coon, President of Vice
```

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Library General Public License instead of this License.

\" te
.TH dbus-binding-tool 1 "26 Feb 2009" "SunOS 5.11" "User Commands"
.SH "NAME"
dbus-binding-tool \- C language GLib bindings generation utility\&.
.SH "SYNOPSIS"
.PP
\fbdbus-binding-tool\fr [-\fb-force\fr] [-\fb-help\fr] [-\fb-ignore-
unsupported\fr] [-\fb-mode=\fIpretty|glib-client|glib-server\fr\fr] [-
\fb-output=\fIfile\fr\fr] [-\fb-prefix=\fIsymbol-prefix\fr\fr] [-\fb-
version\fr] [\fb\fiifile\fr\fr\&...]
.SH "DESCRIPTION"
.PP
\fbdbus-binding-tool\fr is used to expose a GObject via D\-\Bus\&. As
input,
\fbdbus-binding-tool\fr uses a D\-\Bus Introspection XML file\&. As
output,
the client-side or server-side bindings is generated\&. This output
is a header
file which eases the use of a remote D\-\Bus object\&. Output is sent
to standard
out or to the filename specified with the -\fb-output\fr argument\&.
.SH "EXTENDED DESCRIPTION"
.SS ""
.PP

```

The following is a sample D\Bus Introspection XML file which describes an

object that exposes one method, named ManyArgs:

.PP

.nf

```
<?xml version="1.0" encoding="UTF-8" ?>
<node name="/com/example/MyObject">
  <interface name="com\example\MyObject">
    <method name="ManyArgs">
      <arg type="u" name="x" direction="in" />
      <arg type="s" name="str" direction="in" />
      <arg type="d" name="trouble" direction="in" />
      <arg type="d" name="d_ret" direction="out" />
      <arg type="s" name="str_ret" direction="out" />
    </method>
  </interface>
</node>
```

.fi

.PP

\fBdbus-binding-tool\fR supports annotations in the XML format to further

control how the bindings are generated\&.

.SS "client-side bindings"

.PP

When building client-side bindings, the `-fb-mode=glib-client` argument is used\&. The client-side bindings support the `"org\freedesktop\DBus\Glib\NoReply"` annotation\&. This is specified

within the `<method>` tag to indicate that the client is not expecting a reply to the method call, so a reply should not be sent\&. This is often used to speed up rapid method calls where there are no "out" arguments, and not knowing if the method succeeded is an acceptable compromise

to halve the traffic on the bus\&. For example:

.PP

.nf

```
<method name "FooMethod">
  [\&.\&.\&.]
  <annotation name="org\freedesktop\DBus\GLib\NoReply"
value="yes"/>
  [\&.\&.\&.]
</method>
```

.fi

.SS "server-side bindings"

.PP

When building server-side bindings, the `-fb-mode=glib-server` argument is used\&. Also the `-fb-prefix` argument must be used when

building server-side bindings so that functions in the generated output are

prefixed with the specified value\&. The server-side bindings support the

following annotations:

```
.PP
"org\&.freedesktop\&.DBus\&.GLib\&.CSymbol"
.PP
```

This annotation is used to specify the C symbol names for the various types (interface, method, etc\&.), if it differs from the name D\&-Bus generates\&.

```
.PP
.PP
.nf
<interface name="com\&.example\&.MyObject">
  <annotation name="org\&.freedesktop\&.DBus\&.GLib\&.CSymbol"
value="my_object"/>
  [\&.\&.\&.]
  <method name "ManyArgs">
    <annotation name="org\&.freedesktop\&.DBus\&.GLib\&.CSymbol"
value="my_object_many_args"/>
    [\&.\&.\&.]
  </method>
</interface>
```

```
.fi
.PP
"org\&.freedesktop\&.DBus\&.GLib\&.Async"
.PP
```

This annotation marks the method implementation as an asynchronous function, which does not return a response straight away but will send the response at some later point to complete the call\&. This is used to implement non-blocking services where method calls can take time\&.

```
.PP
When a method is asynchronous, the function prototype is different\&. It is required that the function conform to the following rules:
```

```
.sp
.in +2
\ (bu
.mk
.in +3
.rt
The function must return a value of type gboolean; TRUE on success, and FALSE otherwise\&.
```

```
.in -3
\ (bu
.mk
.in +3
.rt
The first parameter is a pointer to an instance of the object\&.
```

```
.in -3
\ (bu
```

```

.mk
.in +3
.rt
Following the object instance pointer are the method input values\&.
.in -3
\ (bu
.mk
.in +3
.rt
The final parameter must be a (DBusGMethodInvocation *)\&. This is
used
when sending the response message back to the client, by calling
dbus_g_method_return or dbus_g_method_return_error\&.
.in -3
.in -2
.PP
For example:
.PP
.nf
<method name "FooMethod">
  [\&.\&.\&.]
  <annotation name="org\&.freedesktop\&.DBus\&.GLib\&.Async"
value="yes"/>
  [\&.\&.\&.]
</method>
.fi
.PP
"org\&.freedesktop\&.DBus\&.GLib\&.Const"
.PP
This attribute can only be applied to "out" <arg> nodes, and
specifies that the parameter is not being copied when returned\&. For
example,
this turns a \&'s\&' argument from a (char **) to a (const char **),
and results in
the argument not being freed by D\&-Bus after the message is sent\&.
For example:
.PP
.nf
  <arg type="u" name="x" direction="out">
    <annotation name="org\&.freedesktop\&.DBus\&.GLib\&.Const"
value=""/>
  </arg>
.fi
.PP
"org\&.freedesktop\&.DBus\&.GLib\&.RetVal"
.PP
This attribute can only be applied to "out" <arg> nodes, and
alters the expected function signature\&. It currently can be set to
two values:
"" or "error"\&. The argument marked with this attribute is
not returned via a pointer argument, but by the function\&'s return
value\&. If the

```

attribute\&'s value is the empty string, the (GError *) argument is also omitted

so there is no standard way to return an error value\&. This is very useful for

interfacing with existing code, as it is possible to match existing APIs\&. If

the attribute\&'s value is "error", then the final argument is a (GError *) as usual\&. For example:

```
.PP
.nf
  <arg type="u" name="x" direction="out">
    <annotation name="org\&.freedesktop\&.DBus\&.GLib\&.RetVal"
value=""/>
  </arg>
```

```
.fi
.SH "OPTIONS"
```

```
.PP
The following options are supported:
```

```
.sp
.ne 2
.mk
\FB-\fB-force\fR\fR
.sp .6
.in +4
```

Overwrite the output file if it already exists with a newer timestamp than the source files\&.

```
.sp
.sp 1
.in -4
.sp
.ne 2
.mk
\FB-\fB-help\fR\fR
.sp .6
.in +4
```

Display usage information\&.

```
.sp
.sp 1
.in -4
.sp
.ne 2
.mk
\FB-\fB-ignore-unsupported\fR\fR
.sp .6
.in +4
```

If set, then unsupported signatures for <method> parameters are ignored\&.

```
.sp
.sp 1
.in -4
.sp
```

```

.ne 2
.mk
\fb-\fb-mode=\fIpretty|glib-client|glib-server\fR\fR\fR
.sp .6
.in +4
If the value is "glib-client", then client bindings are generated\&.
If the value is "glib-server", then server bindings are generated\&.
If the value is "pretty", then the output is in a more human readable
format\&.
.sp
.sp 1
.in -4
.sp
.ne 2
.mk
\fb-\fb-output=\fIfile\fR\fR\fR
.sp .6
.in +4
Specify the output \fIfile\fR\&.
.sp
.sp 1
.in -4
.sp
.ne 2
.mk
\fb-\fb-prefix=\fIsymbol-prefix\fR\fR\fR
.sp .6
.in +4
Functions in the generated output are prefixed with the
\fIsymbol-prefix\fR value\&.
.sp
.sp 1
.in -4
.sp
.ne 2
.mk
\fb-\fb-version\fR\fR
.sp .6
.in +4
Display the version number of the \fbdbus-binding-tool\fR command\&.
.sp
.sp 1
.in -4
.SH "OPERANDS"
.PP
The following operands are supported:
.sp
.ne 2
.mk
\fb\fb\fIfile\fR\fR\fR
.in +16n
.rt

```

A list of one or more input D\ -Bus Introspection XML files to include in the generated output\&.

```
.sp
.sp 1
.in -16n
.SH "FILES"
.PP
```

The following files are used by this application:

```
.sp
.ne 2
.mk
\fb\fb/usr/bin/dbus-binding-tool\fr \fr
.in +32n
.rtf
```

Executable for the D\ -Bus Binding Tool application\&.

```
.sp
.sp 1
.in -32n
.SH "ATTRIBUTES"
.PP

/**

* @defgroup DBusBus Message bus APIs

* @ingroup DBus

* @brief Functions for communicating with the message bus

*

* dbus_bus_get() allows all modules and libraries in a given
* process to share the same connection to the bus daemon by storing
* the connection globally.

*

* All other functions in this module are just convenience functions;
* most of them invoke methods on the bus daemon, by sending method
* call messages to #DBUS_SERVICE_DBUS. These convenience functions
* often make blocking method calls. If you don't want to block,
* you can send the method call messages manually in the same way
* you would any other method call message.

*

* This module is the only one in libdbus that's specific to
* communicating with the message bus daemon. The rest of the API can
* also be used for connecting to another application directly.

*

* @todo right now the default address of the system bus is hardcoded,
* so if you change it in the global config file suddenly you have to
* set DBUS_SYSTEM_BUS_ADDRESS env variable. Might be nice if the
* client lib somehow read the config file, or if the bus on startup
* somehow wrote out its address to a well-known spot, but might also

```

* not be worth it.

/**
 * Registers a connection with the bus. This must be the first
 * thing an application does when connecting to the message bus.
 * If registration succeeds, the unique name will be set,
 * and can be obtained using dbus_bus_get_unique_name().

```

```

*
* This function will block until registration is complete.
*
* If the connection has already registered with the bus
* (determined by checking whether dbus_bus_get_unique_name()
* returns a non-#NULL value), then this function does nothing.
*
* If you use dbus_bus_get() or dbus_bus_get_private() this
* function will be called for you.
*
* @note Just use dbus_bus_get() or dbus_bus_get_private() instead of
* dbus_bus_register() and save yourself some pain. Using
* dbus_bus_register() manually is only useful if you have your
* own custom message bus not found in #DBusBusType.
*
* If you open a bus connection with dbus_connection_open() or
* dbus_connection_open_private() you will have to dbus_bus_register()
* yourself, or make the appropriate registration method calls
* yourself. If you send the method calls yourself, call
* dbus_bus_set_unique_name() with the unique bus name you get from
* the bus.
*
* For shared connections (created with dbus_connection_open()) in a
* multithreaded application, you can't really make the registration
* calls yourself, because you don't know whether some other thread is
* also registering, and the bus will kick you off if you send two
* registration messages.
*
* If you use dbus_bus_register() however, there is a lock that
* keeps both apps from registering at the same time.
*
* The rule in a multithreaded app, then, is that dbus_bus_register()
* must be used to register, or you need to have your own locks that
* all threads in the app will respect.
*
* In a single-threaded application you can register by hand instead
* of using dbus_bus_register(), as long as you check
* dbus_bus_get_unique_name() to see if a unique name has already been
* stored by another thread before you send the registration messages.
*
* @param connection the connection
* @param error place to store errors
* @returns #TRUE on success

/**
 * Sets the unique name of the connection, as assigned by the message
 * bus. Can only be used if you registered with the bus manually
 * (i.e. if you did not call dbus_bus_register()). Can only be called
 * once per connection. After the unique name is set, you can get it
 * with dbus_bus_get_unique_name().
 *
 * The only reason to use this function is to re-implement the
 * equivalent of dbus_bus_register() yourself. One (probably unusual)
 * reason to do that might be to do the bus registration call
 * asynchronously instead of synchronously.
 *
 * @note Just use dbus_bus_get() or dbus_bus_get_private(), or worst
 * case dbus_bus_register(), instead of messing with this
 * function. There's really no point creating pain for yourself by
 * doing things manually.
 *
 * It's hard to use this function safely on shared connections
 * (created by dbus_connection_open()) in a multithreaded application,
 * because only one registration attempt can be sent to the bus. If
 * two threads are both sending the registration message, there is no
 * mechanism in libdbus itself to avoid sending it twice.
 *
 * Thus, you need a way to coordinate which thread sends the
 * registration attempt; which also means you know which thread
 * will call dbus_bus_set_unique_name(). If you don't know
 * about all threads in the app (for example, if some libraries
 * you're using might start libdbus-using threads), then you
 * need to avoid using this function on shared connections.

```

/**
 * Asks the bus to assign the given name to this connection by
invoking
 * the RequestName method on the bus. This method is fully documented
 * in the D-Bus specification. For quick reference, the flags and
 * result codes are discussed here, but the specification is the
 * canonical version of this information.
 *
 * First you should know that for each bus name, the bus stores
 * a queue of connections that would like to own it. Only
 * one owns it at a time - called the primary owner. If the primary
 * owner releases the name or disconnects, then the next owner in the
 * queue atomically takes over.
 *
 * So for example if you have an application
org.freedesktop.TextEditor

```

* and multiple instances of it can be run, you can have all of them
* sitting in the queue. The first one to start up will receive
messages
* sent to org.freedesktop.TextEditor, but if that one exits another
* will become the primary owner and receive messages.
*
* The queue means you don't need to manually watch for the current
owner to
* disappear and then request the name again.
*
* When requesting a name, you can specify several flags.
*
* #DBUS_NAME_FLAG_ALLOW_REPLACEMENT and #DBUS_NAME_FLAG_DO_NOT_QUEUE
* are properties stored by the bus for this connection with respect
to
* each requested bus name. These properties are stored even if the
* connection is queued and does not become the primary owner.
* You can update these flags by calling RequestName again (even if
* you already own the name).
*
* #DBUS_NAME_FLAG_ALLOW_REPLACEMENT means that another requestor of
the
* name can take it away from you by specifying
#DBUS_NAME_FLAG_REPLACE_EXISTING.
*
* #DBUS_NAME_FLAG_DO_NOT_QUEUE means that if you aren't the primary
owner,
* you don't want to be queued up - you only care about being the
* primary owner.
*
* Unlike the other two flags, #DBUS_NAME_FLAG_REPLACE_EXISTING is a
property
* of the individual RequestName call, i.e. the bus does not
persistently
* associate it with the connection-name pair. If a RequestName call
includes
* the #DBUS_NAME_FLAG_REPLACE_EXISTING flag, and the current primary
* owner has #DBUS_NAME_FLAG_ALLOW_REPLACEMENT set, then the current
primary
* owner will be kicked off.
*
* If no flags are given, an application will receive the requested
* name only if the name is currently unowned; and it will NOT give
* up the name if another application asks to take it over using
* #DBUS_NAME_FLAG_REPLACE_EXISTING.
*
* This function returns a result code. The possible result codes
* are as follows.
*
* #DBUS_REQUEST_NAME_REPLY_PRIMARY_OWNER means that the name had no
* existing owner, and the caller is now the primary owner; or that
* the name had an owner, and the caller specified

```

* #DBUS_NAME_FLAG_REPLACE_EXISTING, and the current owner
* specified #DBUS_NAME_FLAG_ALLOW_REPLACEMENT.
*
* #DBUS_REQUEST_NAME_REPLY_IN_QUEUE happens only if the caller does
NOT
* specify #DBUS_NAME_FLAG_DO_NOT_QUEUE and either the current owner
* did NOT specify #DBUS_NAME_FLAG_ALLOW_REPLACEMENT or the caller did
NOT
* specify #DBUS_NAME_FLAG_REPLACE_EXISTING. In this case the caller
ends up
* in a queue to own the name after the current owner gives it up.
*
* #DBUS_REQUEST_NAME_REPLY_EXISTS happens if the name has an owner
* already and the caller specifies #DBUS_NAME_FLAG_DO_NOT_QUEUE
* and either the current owner has NOT specified
* #DBUS_NAME_FLAG_ALLOW_REPLACEMENT or the caller did NOT specify
* #DBUS_NAME_FLAG_REPLACE_EXISTING.
*
* #DBUS_REQUEST_NAME_REPLY_ALREADY_OWNER happens if an application
* requests a name it already owns. (Re-requesting a name is useful if
* you want to change the #DBUS_NAME_FLAG_ALLOW_REPLACEMENT or
* #DBUS_NAME_FLAG_DO_NOT_QUEUE settings.)
*
* When a service represents an application, say "text editor," then
* it should specify #DBUS_NAME_FLAG_ALLOW_REPLACEMENT if it wants
* the last editor started to be the user's editor vs. the first one
* started. Then any editor that can be the user's editor should
* specify #DBUS_NAME_FLAG_REPLACE_EXISTING to either take over
* (last-started-wins) or be queued up (first-started-wins) according
* to whether #DBUS_NAME_FLAG_ALLOW_REPLACEMENT was given.
*
* Conventionally, single-instance applications often offer a command
* line option called --replace which means to replace the current
* instance. To implement this, always set
* #DBUS_NAME_FLAG_ALLOW_REPLACEMENT when you request your
* application's bus name. When you lose ownership of your bus name,
* you need to exit. Look for the signal "NameLost" from
* #DBUS_SERVICE_DBUS and #DBUS_INTERFACE_DBUS (the signal's first
* argument is the bus name that was lost). If starting up without
* --replace, do not specify #DBUS_NAME_FLAG_REPLACE_EXISTING, and
* exit if you fail to become the bus name owner. If --replace is
* given, ask to replace the old owner.
*
* @param connection the connection
* @param name the name to request
* @param flags flags
* @param error location to store the error
* @returns a result code, -1 if error is set

/**
 * Adds a match rule to match messages going through the message bus.
 * The "rule" argument is the string form of a match rule.
 *
 * If you pass #NULL for the error, this function will not
 * block; the match thus won't be added until you flush the
 * connection, and if there's an error adding the match
 * you won't find out about it. This is generally acceptable, since
the
 * possible errors (including a lack of resources in the bus, the
connection
 * having exceeded its quota of active match rules, or the match rule
being
 * unparseable) are generally unrecoverable.
 *
 * If you pass non-#NULL for the error this function will
 * block until it gets a reply. This may be useful when using match
rule keys
 * introduced in recent versions of D-Bus, like 'arg0namespace', to
allow the
 * application to fall back to less efficient match rules supported by
older
 * versions of the daemon if the running version is not new enough; or
when
 * using user-supplied rules rather than rules hard-coded at compile
time.
 *
 * Normal API conventions would have the function return
 * a boolean value indicating whether the error was set,
 * but that would require blocking always to determine
 * the return value.
 *
 * The AddMatch method is fully documented in the D-Bus
 * specification. For quick reference, the format of the
 * match rules is discussed here, but the specification

```

* is the canonical version of this information.
*
* Rules are specified as a string of comma separated
* key/value pairs. An example is
* "type='signal',sender='org.freedesktop.DBus',
* interface='org.freedesktop.DBus',member='Foo',
* path='/bar/foo',destination=':452345.34'"
*
* Possible keys you can match on are type, sender,
* interface, member, path, destination and numbered
* keys to match message args (keys are 'arg0', 'arg1', etc.).
* Omitting a key from the rule indicates
* a wildcard match. For instance omitting
* the member from a match rule but adding a sender would
* let all messages from that sender through regardless of
* the member.
*
* Matches are inclusive not exclusive so as long as one
* rule matches the message will get through. It is important
* to note this because every time a message is received the
* application will be paged into memory to process it. This
* can cause performance problems such as draining batteries
* on embedded platforms.
*
* If you match message args ('arg0', 'arg1', and so forth)
* only string arguments will match. That is, arg0='5' means
* match the string "5" not the integer 5.
*
* Currently there is no way to match against non-string arguments.
*
* A specialised form of wildcard matching on arguments is
* supported for path-like namespaces. If your argument match has
* a 'path' suffix (eg: "arg0path='/some/path/'") then it is
* considered a match if the argument exactly matches the given
* string or if one of them ends in a '/' and is a prefix of the
* other.
*
* Matching on interface is tricky because method call
* messages only optionally specify the interface.
* If a message omits the interface, then it will NOT match
* if the rule specifies an interface name. This means match
* rules on method calls should not usually give an interface.
*
* However, signal messages are required to include the interface
* so when matching signals usually you should specify the interface
* in the match rule.
*
* For security reasons, you can match arguments only up to
* #DBUS_MAXIMUM_MATCH_RULE_ARG_NUMBER.
*
* Match rules have a maximum length of
#DBUS_MAXIMUM_MATCH_RULE_LENGTH

```

* bytes.
*
* Both of these maximums are much higher than you're likely to need,
* they only exist because the D-Bus bus daemon has fixed limits on
* all resource usage.
*
* @param connection connection to the message bus
* @param rule textual form of match rule
* @param error location to store any errors

.TH dbus\ -cleanup\ -sockets 1
.SH NAME
dbus\ -cleanup\ -sockets \- clean up leftover sockets in a directory
.SH SYNOPSIS

```

```
.PP
.B dbus\cleanup\sockets [DIRECTORY]
```

```
.SH DESCRIPTION
```

The `\fIdbus\cleanup\sockets\fp` command cleans up unused D\Bus connection sockets. See <http://www.freedesktop.org/software/dbus/> for more information about the big picture.

```
.PP
If given no arguments, \fIdbus\cleanup\sockets\fp cleans up sockets in the standard default socket directory for the per\user\login\session message bus; this is usually /tmp. Optionally, you can pass a different directory on the command line.
```

```
.PP
On Linux, this program is essentially useless, because D\Bus defaults to using "abstract sockets" that exist only in memory and don't have a corresponding file in /tmp.
```

```
.PP
On most other flavors of UNIX, it's possible for the socket files to leak when programs using D\Bus exit abnormally or without closing their D\Bus connections. Thus, it might be interesting to run dbus\cleanup\sockets in a cron job to mop up any leaked sockets. Or you can just ignore the leaked sockets, they aren't really hurting anything, other than cluttering the output of "ls /tmp"
```

```
.SH AUTHOR
```

`dbus\cleanup\sockets` was adapted by Havoc Pennington from `linc\cleanup\sockets` written by Michael Meeks.

```
.SH BUGS
```

Please send bug reports to the D\Bus mailing list or bug tracker, see <http://www.freedesktop.org/software/dbus/>

/**
 * @defgroup DBusConnection DBusConnection
 * @ingroup DBus
 * @brief Connection to another application
 *
 * A DBusConnection represents a connection to another
 * application. Messages can be sent and received via this connection.
 * The other application may be a message bus; for convenience, the
 * function dbus_bus_get() is provided to automatically open a
 * connection to the well-known message buses.
 *
 * In brief a DBusConnection is a message queue associated with some
 * message transport mechanism such as a socket. The connection
 * maintains a queue of incoming messages and a queue of outgoing
 * messages.
 *
 * Several functions use the following terms:
 * <ul>
 * <li><b>read</b> means to fill the incoming message queue by reading
from the socket</li>
 * <li><b>write</b> means to drain the outgoing queue by writing to
the socket</li>

```

* `dispatch` means to drain the incoming queue by invoking application-provided message handlers

- *
- * The function `dbus_connection_read_write_dispatch()` for example does all
- * three of these things, offering a simple alternative to a main loop.
- * In an application with a main loop, the read/write/dispatch operations are usually separate.
- * The connection provides `#DBusWatch` and `#DBusTimeout` objects to the main loop. These are used to know when reading, writing, or dispatching should be performed.
- * Incoming messages are processed by calling `dbus_connection_dispatch()`. `dbus_connection_dispatch()` runs any handlers registered for the topmost message in the message queue, then discards the message, then returns.
- * `dbus_connection_get_dispatch_status()` indicates whether messages are currently in the queue that need dispatching.
- * `dbus_connection_set_dispatch_status_function()` allows you to set a function to be used to monitor the dispatch status.
- * If you're using GLib or Qt add-on libraries for D-Bus, there are special convenience APIs in those libraries that hide all the details of dispatch and watch/timeout monitoring. For example, `dbus_connection_setup_with_g_main()`.
- * If you aren't using these add-on libraries, but want to process messages asynchronously, you must manually call `dbus_connection_set_dispatch_status_function()`, `dbus_connection_set_watch_functions()`, `dbus_connection_set_timeout_functions()` providing appropriate functions to integrate the connection with your application's main loop. This can be tricky to get right; main loops are not simple.
- * If you don't need to be asynchronous, you can ignore `#DBusWatch`, `#DBusTimeout`, and `dbus_connection_dispatch()`. Instead, `dbus_connection_read_write_dispatch()` can be used.
- * Or, in *very* simple applications, `dbus_connection_pop_message()` may be all you need, allowing you to avoid setting up any handler functions (see `dbus_connection_add_filter()`, `dbus_connection_register_object_path()` for more on handlers).
- * When you use `dbus_connection_send()` or one of its variants to send a message, the message is added to the outgoing queue. It's actually written to the network later; either in

```

* dbus_watch_handle() invoked by your main loop, or in
* dbus_connection_flush() which blocks until it can write out the
* entire outgoing queue. The GLib/Qt add-on libraries again
* handle the details here for you by setting up watch functions.
*
* When a connection is disconnected, you are guaranteed to get a
* signal "Disconnected" from the interface
* #DBUS_INTERFACE_LOCAL, path
* #DBUS_PATH_LOCAL.
*
* You may not drop the last reference to a #DBusConnection
* until that connection has been disconnected.
*
* You may dispatch the unprocessed incoming message queue even if the
* connection is disconnected. However, "Disconnected" will always be
* the last message in the queue (obviously no messages are received
* after disconnection).
*
* After calling dbus_threads_init(), #DBusConnection has thread
* locks and drops them when invoking user callbacks, so in general is
* transparently threadsafe. However, #DBusMessage does NOT have
* thread locks; you must not send the same message to multiple
* #DBusConnection if those connections will be used from different
threads,
* for example.
*
* Also, if you dispatch or pop messages from multiple threads, it
* may work in the sense that it won't crash, but it's tough to
imagine
* sane results; it will be completely unpredictable which messages
* go to which threads.
*
* It's recommended to dispatch from a single thread.
*
* The most useful function to call from multiple threads at once
* is dbus_connection_send_with_reply_and_block(). That is,
* multiple threads can make method calls at the same time.
*
* If you aren't using threads, you can use a main loop and
* dbus_pending_call_set_notify() to achieve a similar result.

 * Queues incoming messages and sends outgoing messages for this
 * connection, optionally blocking in the process. Each call to
 * _dbus_connection_do_iteration_unlocked() will call select() or
 * poll() one
 * time and then read or write data if possible.
 */

```

```

* The purpose of this function is to be able to flush outgoing
* messages or queue up incoming messages without returning
* control to the application and causing reentrancy weirdness.
*
* The flags parameter allows you to specify whether to
* read incoming messages, write outgoing messages, or both,
* and whether to block if no immediate action is possible.
*
* The timeout_milliseconds parameter does nothing unless the
* iteration is blocking.
*
* If there are no outgoing messages and DBUS_ITERATION_DO_READING
* wasn't specified, then it's impossible to block, even if
* you specify DBUS_ITERATION_BLOCK; in that case the function
* returns immediately.
*
* If pending is not NULL then a check is made if the pending call
* is completed after the io path has been required. If the call
* has been completed nothing is done. This must be done since
* the _dbus_connection_acquire_io_path releases the connection
* lock for a while.
*
* Called with connection lock held.
*
* @param connection the connection.
* @param pending the pending call that should be checked or NULL
* @param flags iteration flags.
* @param timeout_milliseconds maximum blocking time, or -1 for no
limit.

/**
 * @addtogroup DBusConnection
 *
 * @{
 */

/**
 * Gets a connection to a remote address. If a connection to the given
 * address already exists, returns the existing connection with its
 * reference count incremented. Otherwise, returns a new connection
 * and saves the new connection for possible re-use if a future call
 * to dbus_connection_open() asks to connect to the same server.
 *
 * Use dbus_connection_open_private() to get a dedicated connection
 * not shared with other callers of dbus_connection_open().
 *
 * If the open fails, the function returns #NULL, and provides a
 * reason for the failure in the error parameter. Pass #NULL for the
 * error parameter if you aren't interested in the reason for
 * failure.
 *
 * Because this connection is shared, no user of the connection
 * may call dbus_connection_close(). However, when you are done with
the
 * connection you should call dbus_connection_unref().
 *
 * @note Prefer dbus_connection_open() to
dbus_connection_open_private()
 * unless you have good reason; connections are expensive enough
 * that it's wasteful to create lots of connections to the same
 * server.
 *
 * @param address the address.
 * @param error address where an error can be returned.
 * @returns new connection, or #NULL on failure.

 * Opens a new, dedicated connection to a remote address. Unlike
 * dbus_connection_open(), always creates a new connection.
 * This connection will not be saved or recycled by libdbus.
 *
 * If the open fails, the function returns #NULL, and provides a
 * reason for the failure in the error parameter. Pass #NULL for the
 * error parameter if you aren't interested in the reason for
 * failure.
 *
 * When you are done with this connection, you must
 * dbus_connection_close() to disconnect it,
 * and dbus_connection_unref() to free the connection object.
 *
 * (The dbus_connection_close() can be skipped if the
 * connection is already known to be disconnected, for example
 * if you are inside a handler for the Disconnected signal.)
 *
 * @note Prefer dbus_connection_open() to
dbus_connection_open_private()
 * unless you have good reason; connections are expensive enough
 * that it's wasteful to create lots of connections to the same
 * server.
 *
 * @param address the address.

/**
* Closes a private connection, so no further data can be sent or
received.
* This disconnects the transport (such as a socket) underlying the
* connection.

```

```

*
* Attempts to send messages after closing a connection are safe, but
will result in
* error replies generated locally in libdbus.
*
* This function does not affect the connection's reference count.
It's
* safe to close a connection more than once; all calls after the
* first do nothing. It's impossible to "reopen" a connection, a
* new connection must be created. This function may result in a call
* to the DBusDispatchStatusFunction set with
* dbus_connection_set_dispatch_status_function(), as the disconnect
* message it generates needs to be dispatched.
*
* If a connection is dropped by the remote application, it will
* close itself.
*
* You must close a connection prior to releasing the last reference
to
* the connection. If you dbus_connection_unref() for the last time
* without closing the connection, the results are undefined; it
* is a bug in your program and libdbus will try to print a warning.
*
* You may not close a shared connection. Connections created with
* dbus_connection_open() or dbus_bus_get() are shared.
* These connections are owned by libdbus, and applications should
* only unref them, never close them. Applications can know it is
* safe to unref these connections because libdbus will be holding a
* reference as long as the connection is open. Thus, either the
* connection is closed and it is OK to drop the last reference,
* or the connection is open and the app knows it does not have the
* last reference.
*
* Connections created with dbus_connection_open_private() or
* dbus_bus_get_private() are not kept track of or referenced by
* libdbus. The creator of these connections is responsible for
* calling dbus_connection_close() prior to releasing the last
* reference, if the connection is not already disconnected.

/**
 * Queues a message to send, as with dbus_connection_send(),
 * but also returns a #DBusPendingCall used to receive a reply to the
 * message. If no reply is received in the given timeout_milliseconds,
 * this function expires the pending reply and generates a synthetic
 * error reply (generated in-process, not by the remote application)
 * indicating that a timeout occurred.
 *
 * A #DBusPendingCall will see a reply message before any filters or
 * registered object path handlers. See dbus_connection_dispatch() for
 * details on when handlers are run.
 *
 * A #DBusPendingCall will always see exactly one reply message,
 * unless it's cancelled with dbus_pending_call_cancel().
 *
 * If #NULL is passed for the pending_return, the #DBusPendingCall
 * will still be generated internally, and used to track
 * the message reply timeout. This means a timeout error will
 * occur if no reply arrives, unlike with dbus_connection_send().
 *
 * If -1 is passed for the timeout, a sane default timeout is used. -1
 * is typically the best value for the timeout for this reason, unless

```

```

* you want a very short or very long timeout. If
#DBUS_TIMEOUT_INFINITE is
* passed for the timeout, no timeout will be set and the call will
block
* forever.
*
* @warning if the connection is disconnected or you try to send Unix
* file descriptors on a connection that does not support them, the
* #DBusPendingCall will be set to #NULL, so be careful with this.
*
* @param connection the connection
* @param message the message to send
* @param pending_return return location for a #DBusPendingCall
* object, or #NULL if connection is disconnected or when you try to
* send Unix file descriptors on a connection that does not support
* them.
* @param timeout_milliseconds timeout in milliseconds, -1 (or
* #DBUS_TIMEOUT_USE_DEFAULT) for default or #DBUS_TIMEOUT_INFINITE
for no
* timeout
* @returns #FALSE if no memory, #TRUE otherwise.

/**
 * This function is intended for use with applications that don't want
 * to write a main loop and deal with #DBusWatch and #DBusTimeout. An
 * example usage would be:
 *
 * @code
 *     while (dbus_connection_read_write_dispatch (connection, -1))
 *         ; // empty loop body
 * @endcode
 *
 * In this usage you would normally have set up a filter function to
look
 * at each message as it is dispatched. The loop terminates when the
last
 * message from the connection (the disconnected signal) is processed.
 *
 * If there are messages to dispatch, this function will
 * dbus_connection_dispatch() once, and return. If there are no
 * messages to dispatch, this function will block until it can read or
 * write, then read or write, then return.
 *
 * The way to think of this function is that it either makes some sort
 * of progress, or it blocks. Note that, while it is blocked on I/O,
it
 * cannot be interrupted (even by other threads), which makes this
function
 * unsuitable for applications that do more than just react to
received

```

```

* messages.
*
* The return value indicates whether the disconnect message has been
* processed, NOT whether the connection is connected. This is
* important because even after disconnecting, you want to process any
* messages you received prior to the disconnect.
*
* @param connection the connection
* @param timeout_milliseconds max time to block or -1 for infinite
* @returns #TRUE if the disconnect message has not been processed

/**
 * Returns the first-received message from the incoming message queue,
 * removing it from the queue. The caller owns a reference to the
 * returned message. If the queue is empty, returns #NULL.
 *
 * This function bypasses any message handlers that are registered,
 * and so using it is usually wrong. Instead, let the main loop invoke
 * dbus_connection_dispatch(). Popping messages manually is only
 * useful in very simple programs that don't share a #DBusConnection
 * with any libraries or other modules.
 *
 * There is a lock that covers all ways of accessing the incoming
message
 * queue, so dbus_connection_dispatch(),
dbus_connection_pop_message(),
 * dbus_connection_borrow_message(), etc. will all block while one of
the others
 * in the group is running.

/**
 * Processes any incoming data.
 *
 * If there's incoming raw data that has not yet been parsed, it is
 * parsed, which may or may not result in adding messages to the
 * incoming queue.
 *
 * The incoming data buffer is filled when the connection reads from
 * its underlying transport (such as a socket). Reading usually
 * happens in dbus_watch_handle() or dbus_connection_read_write().
 *
 * If there are complete messages in the incoming queue,

```

```

* dbus_connection_dispatch() removes one message from the queue and
* processes it. Processing has three steps.
*
* First, any method replies are passed to #DBusPendingCall or
* dbus_connection_send_with_reply_and_block() in order to
* complete the pending method call.
*
* Second, any filters registered with dbus_connection_add_filter()
* are run. If any filter returns #DBUS_HANDLER_RESULT_HANDLED
* then processing stops after that filter.
*
* Third, if the message is a method call it is forwarded to
* any registered object path handlers added with
* dbus_connection_register_object_path() or
* dbus_connection_register_fallback().
*
* A single call to dbus_connection_dispatch() will process at most
* one message; it will not clear the entire message queue.
*
* Be careful about calling dbus_connection_dispatch() from inside a
* message handler, i.e. calling dbus_connection_dispatch()
* recursively. If threads have been initialized with a recursive
* mutex function, then this will not deadlock; however, it can
* certainly confuse your application.
*

/**
 * Sets the watch functions for the connection. These functions are
 * responsible for making the application's main loop aware of file
 * descriptors that need to be monitored for events, using select() or
 * poll(). When using Qt, typically the DBusAddWatchFunction would
 * create a QSocketNotifier. When using GLib, the DBusAddWatchFunction
 * could call g_io_add_watch(), or could be used as part of a more
 * elaborate GSource. Note that when a watch is added, it may
 * not be enabled.
 *
 * The DBusWatchToggledFunction notifies the application that the
 * watch has been enabled or disabled. Call dbus_watch_get_enabled()
 * to check this. A disabled watch should have no effect, and enabled
 * watch should be added to the main loop. This feature is used
 * instead of simply adding/removing the watch because
 * enabling/disabling can be done without memory allocation. The
 * toggled function may be NULL if a main loop re-queries
 * dbus_watch_get_enabled() every time anyway.
 *
 * The DBusWatch can be queried for the file descriptor to watch using
 * dbus_watch_get_unix_fd() or dbus_watch_get_socket(), and for the
 * events to watch for using dbus_watch_get_flags(). The flags
 * returned by dbus_watch_get_flags() will only contain
 * DBUS_WATCH_READABLE and DBUS_WATCH_WRITABLE, never
 * DBUS_WATCH_HANGUP or DBUS_WATCH_ERROR; all watches implicitly
 * include a watch for hangups, errors, and other exceptional
 * conditions.
 *
 * Once a file descriptor becomes readable or writable, or an
exception
 * occurs, dbus_watch_handle() should be called to
 * notify the connection of the file descriptor's condition.
 *
 * dbus_watch_handle() cannot be called during the

```

```

* DbusAddWatchFunction, as the connection will not be ready to handle
* that watch yet.
*
* It is not allowed to reference a DbusWatch after it has been passed
* to remove_function.
*
* If #FALSE is returned due to lack of memory, the failure may be due
* to a #FALSE return from the new add_function. If so, the
* add_function may have been called successfully one or more times,
* but the remove_function will also have been called to remove any
* successful adds. i.e. if #FALSE is returned the net result
* should be that dbus_connection_set_watch_functions() has no effect,
* but the add_function and remove_function may have been called.
*
* @note The thread lock on DbusConnection is held while
* watch functions are invoked, so inside these functions you
* may not invoke any methods on DbusConnection or it will deadlock.
* See the comments in the code or
http://lists.freedesktop.org/archives/dbus/2007-July/tread.html#8144
* if you encounter this issue and want to attempt writing a patch.
*

messages
 * received on this connection. Messages count toward the maximum
until
 * they are finalized. When the maximum is reached, the connection
will
 * not read more data until some messages are finalized.
 *
 * The semantics of the maximum are: if outstanding messages are
 * already above the maximum, additional messages will not be read.
 * The semantics are not: if the next message would cause us to exceed
 * the maximum, we don't read it. The reason is that we don't know the
 * size of a message until after we read it.

```

```

*
* Thus, the max live messages size can actually be exceeded
* by up to the maximum size of a single message.
*
* Also, if we read say 1024 bytes off the wire in a single read(),
* and that contains a half-dozen small messages, we may exceed the
* size max by that amount. But this should be inconsequential.
*
* This does imply that we can't call read() with a buffer larger
* than we're willing to exceed this limit by.

.SH NAME
dbus\--daemon \-- Message bus daemon
.SH SYNOPSIS
.PP
.B dbus\--daemon
dbus\--daemon [\--version] [\--session] [\--system] [\--config\--
file=FILE]
[\--print\--address[=DESCRIPTOR]] [\--print\--pid[=DESCRIPTOR]] [\--\--
fork]

.SH DESCRIPTION
\fi dbus\--daemon\fp is the D\--Bus message bus daemon. See
http://www.freedesktop.org/software/dbus/ for more information about

```

the big picture. D\ -Bus is first a library that provides one\ -to\ -one communication between any two applications; \fIdbus\ -daemon\ fP is an application that uses this library to implement a message bus daemon. Multiple programs connect to the message bus daemon and can exchange messages with one another.

.PP

There are two standard message bus instances: the systemwide message bus

(installed on many systems as the "messagebus" init service) and the per\ -user\ -login\ -session message bus (started each time a user logs in).

\fIdbus\ -daemon\ fP is used for both of these instances, but with a different configuration file.

.PP

The \-\ -session option is equivalent to

"\-\ -config\ -file=/etc/dbus\ -1/session.conf" and the \-\ -system option is equivalent to

"\-\ -config\ -file=/etc/dbus\ -1/system.conf". By creating additional configuration files and using the \-\ -config\ -file option, additional special\ -purpose message bus daemons could be created.

.PP

The systemwide daemon is normally launched by an init script, standardly called simply "messagebus".

.PP

The systemwide daemon is largely used for broadcasting system events, such as changes to the printer queue, or adding/removing devices.

.PP

The per\ -session daemon is used for various interprocess communication among desktop applications (however, it is not tied to X or the GUI in any way).

.PP

SIGHUP will cause the D\ -Bus daemon to PARTIALLY reload its configuration file and to flush its user/group information caches.

Some configuration changes would require kicking all apps off the bus; so they will

only take effect if you restart the daemon. Policy changes should take effect

with SIGHUP.

.SH OPTIONS

The following options are supported:

.TP

.I "\-\ -config\ -file=FILE"

Use the given configuration file.

.TP

.I "\-\ -fork"

Force the message bus to fork and become a daemon, even if the configuration file does not specify that it should.

In most contexts the configuration file already gets this right, though.

.I "\-\ -nofork"

Force the message bus not to fork and become a daemon, even if the configuration file specifies that it should.

.TP

.I "\-\'-print\'-address[=DESCRIPTOR]"

Print the address of the message bus to standard output, or to the given file descriptor. This is used by programs that launch the message bus.

.TP

.I "\-\'-print\'-pid[=DESCRIPTOR]"

Print the process ID of the message bus to standard output, or to the given file descriptor. This is used by programs that launch the message bus.

.TP

.I "\-\'-session"

Use the standard configuration file for the per\'-login\'-session message bus.

.TP

.I "\-\'-system"

Use the standard configuration file for the systemwide message bus.

.TP

.I "\-\'-version"

Print the version of the daemon.

.TP

.I "\-\'-introspect"

Print the introspection information for all D\'-Bus internal interfaces.

.TP

.I "\-\'-address[=ADDRESS]"

Set the address to listen on. This option overrides the address configured in the configuration file.

.TP

.I "\-\'-systemd\'-activation"

Enable systemd\'-style service activation. Only useful in conjunction with the systemd system and session manager on Linux.

.TP

.I "\-\'-nopicfile"

Don't write a PID file even if one is configured in the configuration files.

.SH CONFIGURATION FILE

A message bus daemon has a configuration file that specializes it for a particular application. For example, one configuration file might set up the message bus to be a systemwide message bus, while another might set it up to be a per\'-user\'-login\'-session bus.

.PP

The configuration file also establishes resource limits, security parameters, and so forth.

.PP

The configuration file is not part of any interoperability specification and its backward compatibility is not guaranteed; this

document is documentation, not specification.

.PP

The standard systemwide and per-session message bus setups are configured in the files `"/etc/dbus-1/system.conf"` and `"/etc/dbus-1/session.conf"`. These files normally `<include>` a `system-1-local.conf` or `session-1-local.conf`; you can put local overrides in those files to avoid modifying the primary configuration files.

.PP

The configuration file is an XML document. It must have the following doctype declaration:

.nf

```
<!DOCTYPE busconfig PUBLIC "-//freedesktop//DTD D-Bus Bus
Configuration 1.0//EN"
"http://www.freedesktop.org/standards/dbus/1.0/busconfig.dtd">
```

.fi

.PP

The following elements may be present in the configuration file.

.TP

.I "<busconfig>"

.PP

Root element.

.TP

.I "<type>"

.PP

The well-known type of the message bus. Currently known values are "system" and "session"; if other values are set, they should be either added to the D-Bus specification, or namespaced. The last `<type>` element "wins" (previous values are ignored). This element only controls which message bus specific environment variables are set in activated clients. Most of the policy that distinguishes a session bus from the system bus is controlled from the other elements in the configuration file.

.PP

If the well-known type of the message bus is "session", then the `DBUS_STARTER_BUS_TYPE` environment variable will be set to "session" and the `DBUS_SESSION_BUS_ADDRESS` environment variable will be set to the address of the session bus. Likewise, if the type of the message bus is "system", then the `DBUS_STARTER_BUS_TYPE` environment variable will be set to "system" and the `DBUS_SESSION_BUS_ADDRESS` environment variable will be set to the address of the system bus (which is normally well known anyway).

.PP
Example: <type>session</type>

.TP
.I "<include>"

.PP
Include a file <include>filename.conf</include> at this point. If the filename is relative, it is located relative to the configuration file doing the including.

.PP
<include> has an optional attribute "ignore_missing=(yes|no)" which defaults to "no" if not provided. This attribute controls whether it's a fatal error for the included file to be absent.

.TP
.I "<includedir>"

.PP
Include all files in <includedir>foo.d</includedir> at this point. Files in the directory are included in undefined order. Only files ending in ".conf" are included.

.PP
This is intended to allow extension of the system bus by particular packages. For example, if CUPS wants to be able to send out notification of printer queue changes, it could install a file to /etc/dbus\-1/system.d that allowed all apps to receive this message and allowed the printer daemon user to send it.

.TP
.I "<user>"

.PP
The user account the daemon should run as, as either a username or a UID. If the daemon cannot change to this UID on startup, it will exit. If this element is not present, the daemon will not change or care about its UID.

.PP
The last <user> entry in the file "wins", the others are ignored.

.PP
The user is changed after the bus has completed initialization. So sockets etc. will be created before changing user, but no data will be read from clients before changing user. This means that sockets and PID files can be created in a location that requires root privileges for writing.

.TP
.I "<fork>"

.PP
If present, the bus daemon becomes a real daemon (forks into the background, etc.). This is generally used rather than the `--fork` command line option.

.TP
.I "<keep_umask>"

.PP
If present, the bus daemon keeps its original umask when forking. This may be useful to avoid affecting the behavior of child processes.

.TP
.I "<listen>"

.PP
Add an address that the bus should listen on. The address is in the standard D\--Bus format that contains a transport name plus possible parameters/options.

.PP
Example: `<listen>unix:path=/tmp/foo</listen>`

.PP
Example: `<listen>tcp:host=localhost,port=1234</listen>`

.PP
If there are multiple `<listen>` elements, then the bus listens on multiple addresses. The bus will pass its address to started services or other interested parties with the last address given in `<listen>` first. That is, apps will try to connect to the last `<listen>` address first.

.PP
tcp sockets can accept IPv4 addresses, IPv6 addresses or hostnames. If a hostname resolves to multiple addresses, the server will bind to all of them. The `family=ipv4` or `family=ipv6` options can be used to force it to bind to a subset of addresses

.PP
Example: `<listen>tcp:host=localhost,port=0,family=ipv4</listen>`

.PP
A special case is using a port number of zero (or omitting the port), which means to choose an available port selected by the operating system. The port number chosen can be obtained with the `--print-address` command line parameter and will be present in other cases where the server reports its own address, such as when `DBUS_SESSION_BUS_ADDRESS` is set.

.PP

Example: <listen>tcp:host=localhost,port=0</listen>

.PP

tcp addresses also allow a bind=hostname option, which will override the host option specifying what address to bind to, without changing the address reported by the bus. The bind option can also take a special name '*' to cause the bus to listen on all local address (INADDR_ANY). The specified host should be a valid name of the local machine or weird stuff will happen.

.PP

Example: <listen>tcp:host=localhost,bind=*,port=0</listen>

.TP

.I "<auth>"

.PP

Lists permitted authorization mechanisms. If this element doesn't exist, then all known mechanisms are allowed. If there are multiple <auth> elements, all the listed mechanisms are allowed. The order in which mechanisms are listed is not meaningful.

.PP

Example: <auth>EXTERNAL</auth>

.PP

Example: <auth>DBUS_COOKIE_SHA1</auth>

.TP

.I "<servicedir>"

.PP

Adds a directory to scan for .service files. Directories are scanned starting with the last to appear in the config file (the first .service file found that provides a particular service will be used).

.PP

Service files tell the bus how to automatically start a program. They are primarily used with the per\ -user\ -session bus, not the systemwide bus.

.TP

.I "<standard_session_servicedirs/>"

.PP

<standard_session_servicedirs/> is equivalent to specifying a series of <servicedir/> elements for each of the data directories in the "XDG Base Directory Specification" with the subdirectory "dbus\ -1/services",

so for example `"/usr/share/dbus-1/services"` would be among the directories searched.

.PP

The "XDG Base Directory Specification" can be found at <http://freedesktop.org/wiki/Standards/basedir-spec> if it hasn't moved, otherwise try your favorite search engine.

.PP

The `<standard_session_servicedirs/>` option is only relevant to the `per\-user\-session bus` daemon defined in `/etc/dbus-1/session.conf`. Putting it in any other configuration file would probably be nonsense.

.TP

.I "`<standard_system_servicedirs/>`"

.PP

`<standard_system_servicedirs/>` specifies the standard system-wide activation directories that should be searched for service files. This option defaults to `/usr/share/dbus-1/system-services`.

.PP

The `<standard_system_servicedirs/>` option is only relevant to the `per\-system bus` daemon defined in `/etc/dbus-1/system.conf`. Putting it in any other configuration file would probably be nonsense.

.TP

.I "`<servicehelper/>`"

.PP

`<servicehelper/>` specifies the setuid helper that is used to launch system daemons with an alternate user. Typically this should be the `dbus-daemon-launch-helper` executable located in `libexec`.

.PP

The `<servicehelper/>` option is only relevant to the `per\-system bus` daemon defined in `/etc/dbus-1/system.conf`. Putting it in any other configuration file would probably be nonsense.

.TP

.I "`<limit>`"

.PP

`<limit>` establishes a resource limit. For example:

.nf

```
<limit name="max_message_size">64</limit>
```

```
<limit name="max_completed_connections">512</limit>
```

.fi

.PP

The name attribute is mandatory.
Available limit names are:

```
.nf
    "max_incoming_bytes"      : total size in bytes of messages
                              incoming from a single connection
    "max_incoming_unix_fds"  : total number of unix fds of
messages
                              incoming from a single connection
    "max_outgoing_bytes"     : total size in bytes of messages
                              queued up for a single connection
    "max_outgoing_unix_fds"  : total number of unix fds of
messages
                              queued up for a single connection
    "max_message_size"       : max size of a single message in
                              bytes
    "max_message_unix_fds"   : max unix fds of a single message
    "service_start_timeout"  : milliseconds (thousandths) until
                              a started service has to connect
    "auth_timeout"           : milliseconds (thousandths) a
                              connection is given to
                              authenticate
    "max_completed_connections" : max number of authenticated
connections
    "max_incomplete_connections" : max number of unauthenticated
                              connections
    "max_connections_per_user" : max number of completed
connections from
                              the same user
    "max_pending_service_starts" : max number of service launches in
                              progress at the same time
    "max_names_per_connection" : max number of names a single
                              connection can own
    "max_match_rules_per_connection": max number of match rules for
a single
                              connection
    "max_replies_per_connection" : max number of pending method
                              replies per connection
                              (number of calls\-in\-progress)
    "reply_timeout"          : milliseconds (thousandths)
                              until a method call times out
.fi
```

.PP

The max incoming/outgoing queue sizes allow a new message to be queued if one byte remains below the max. So you can in fact exceed the max by max_message_size.

.PP

max_completed_connections divided by max_connections_per_user is the

number of users that can work together to denial\of\service all other users by using up all connections on the systemwide bus.

.PP

Limits are normally only of interest on the systemwide bus, not the user session buses.

.TP

.I "<policy>"

.PP

The <policy> element defines a security policy to be applied to a particular set of connections to the bus. A policy is made up of <allow> and <deny> elements. Policies are normally used with the systemwide bus; they are analogous to a firewall in that they allow expected traffic and prevent unexpected traffic.

.PP

Currently, the system bus has a default\deny policy for sending method calls and owning bus names. Everything else, in particular reply messages, receive checks, and signals has a default allow policy.

.PP

In general, it is best to keep system services as small, targeted programs which run in their own process and provide a single bus name. Then, all that is needed is an <allow> rule for the "own" permission to let the process claim the bus name, and a "send_destination" rule to allow traffic from some or all uids to your service.

.PP

The <policy> element has one of four attributes:

.nf

```
context="(default|mandatory)"
at_console="(true|false)"
user="username or userid"
group="group name or gid"
```

.fi

.PP

Policies are applied to a connection as follows:

.nf

```
\- all context="default" policies are applied
```

```
\- all group="connection's user's group" policies are applied
   in undefined order
\- all user="connection's auth user" policies are applied
   in undefined order
\- all at_console="true" policies are applied
\- all at_console="false" policies are applied
\- all context="mandatory" policies are applied
.fi
```

```
.PP
Policies applied later will override those applied earlier,
when the policies overlap. Multiple policies with the same
user/group/context are applied in the order they appear
in the config file.
```

```
.TP
.I "<deny>"
.I "<allow>"
```

```
.PP
A <deny> element appears below a <policy> element and prohibits some
action. The <allow> element makes an exception to previous <deny>
statements, and works just like <deny> but with the inverse meaning.
```

```
.PP
The possible attributes of these elements are:
.nf
```

```
send_interface="interface_name"
send_member="method_or_signal_name"
send_error="error_name"
send_destination="name"
send_type="method_call" | "method_return" | "signal" | "error"
send_path="/path/name"

receive_interface="interface_name"
receive_member="method_or_signal_name"
receive_error="error_name"
receive_sender="name"
receive_type="method_call" | "method_return" | "signal" | "error"
receive_path="/path/name"

send_requested_reply="true" | "false"
receive_requested_reply="true" | "false"

eavesdrop="true" | "false"

own="name"
own_prefix="name"
user="username"
group="groupname"
```

```
.fi
```

.PP

Examples:

.nf

```
<deny send_destination="org.freedesktop.Service"
send_interface="org.freedesktop.System" send_member="Reboot"/>
<deny send_destination="org.freedesktop.System"/>
<deny receive_sender="org.freedesktop.System"/>
<deny user="john"/>
<deny group="enemies"/>
```

.fi

.PP

The `<deny>` element's attributes determine whether the deny "matches" a particular action. If it matches, the action is denied (unless later rules in the config file allow it).

.PP

`send_destination` and `receive_sender` rules mean that messages may not be sent to or received from the *owner* of the given name, not that they may not be sent *to that name*. That is, if a connection owns services A, B, C, and sending to A is denied, sending to B or C will not work either.

.PP

The other `send_*` and `receive_*` attributes are purely textual/`by\`-value matches against the given field in the message header.

.PP

"Eavesdropping" occurs when an application receives a message that was explicitly addressed to a name the application does not own, or is a reply to such a message. Eavesdropping thus only applies to messages that are addressed to services and replies to such messages (i.e. it does not apply to signals).

.PP

For `<allow>`, `eavesdrop="true"` indicates that the rule matches even when eavesdropping. `eavesdrop="false"` is the default and means that the rule only allows messages to go to their specified recipient. For `<deny>`, `eavesdrop="true"` indicates that the rule matches only when eavesdropping. `eavesdrop="false"` is the default for `<deny>` also, but here it means that the rule applies always, even when not eavesdropping. The `eavesdrop` attribute can only be combined with `send` and `receive` rules (with `send_*` and `receive_*` attributes).

.PP

The `[send|receive]_requested_reply` attribute works similarly to the `eavesdrop` attribute. It controls whether the `<deny>` or `<allow>` matches a reply that is expected (corresponds to a previous method call message). This attribute only makes sense for reply messages (errors and method returns), and is ignored for other message types.

.PP

For `<allow>`, `[send|receive]_requested_reply="true"` is the default and indicates that only requested replies are allowed by the

rule. [send|receive]_requested_reply="false" means that the rule allows any reply even if unexpected.

.PP

For <deny>, [send|receive]_requested_reply="false" is the default but indicates that the rule matches only when the reply was not requested. [send|receive]_requested_reply="true" indicates that the rule applies always, regardless of pending reply state.

.PP

user and group denials mean that the given user or group may not connect to the message bus.

.PP

For "name", "username", "groupname", etc. the character "*" can be substituted, meaning "any." Complex globs like "foo.bar.*" aren't allowed for now because they'd be work to implement and maybe encourage sloppy security anyway.

.PP

<allow own_prefix="a.b"/> allows you to own the name "a.b" or any name whose first dot-separated elements are "a.b": in particular, you can own "a.b.c" or "a.b.c.d", but not "a.bc" or "a.c". This is useful when services like Telepathy and ReserveDevice define a meaning for subtrees of well-known names, such as org.freedesktop.Telepathy.ConnectionManager.(anything) and org.freedesktop.ReserveDevice1.(anything).

.PP

It does not make sense to deny a user or group inside a <policy> for a user or group; user/group denials can only be inside context="default" or context="mandatory" policies.

.PP

A single <deny> rule may specify combinations of attributes such as send_destination and send_interface and send_type. In this case, the denial applies only if both attributes match the message being denied. e.g. <deny send_interface="foo.bar" send_destination="foo.blah"/> would deny messages with the given interface AND the given bus name. To get an OR effect you specify multiple <deny> rules.

.PP

You can't include both send_ and receive_ attributes on the same rule, since "whether the message can be sent" and "whether it can be received" are evaluated separately.

.PP

Be careful with send_interface/receive_interface, because the

interface field in messages is optional. In particular, do NOT specify `<deny send_interface="org.foo.Bar"/>`! This will cause no\-interface messages to be blocked for all services, which is almost certainly not what you intended. Always use rules of the form: `<deny send_interface="org.foo.Bar" send_destination="org.foo.Service"/>`

.TP
.I "<selinux>"

.PP
The `<selinux>` element contains settings related to Security Enhanced Linux.
More details below.

.TP
.I "<associate>"

.PP
An `<associate>` element appears below an `<selinux>` element and creates a mapping. Right now only one kind of association is possible:
.nf
 `<associate own="org.freedesktop.Foobar" context="foo_t"/>`
.fi

.PP
This means that if a connection asks to own the name "org.freedesktop.Foobar" then the source context will be the context of the connection and the target context will be "foo_t" \- see the short discussion of SELinux below.

.PP
Note, the context here is the target context when requesting a name, NOT the context of the connection owning the name.

.PP
There's currently no way to set a default for owning any name, if we add this syntax it will look like:
.nf
 `<associate own="*" context="foo_t"/>`
.fi
If you find a reason this is useful, let the developers know. Right now the default will be the security context of the bus itself.

.PP
If two `<associate>` elements specify the same name, the element appearing later in the configuration file will be used.

.SH SELinux

.PP

See <http://www.nsa.gov/selinux/> for full details on SELinux. Some useful excerpts:

.IP "" 8

Every subject (process) and object (e.g. file, socket, IPC object, etc) in the system is assigned a collection of security attributes, known as a security context. A security context contains all of the security attributes associated with a particular subject or object that are relevant to the security policy.

.IP "" 8

In order to better encapsulate security contexts and to provide greater efficiency, the policy enforcement code of SELinux typically handles security identifiers (SIDs) rather than security contexts. A SID is an integer that is mapped by the security server to a security context at runtime.

.IP "" 8

When a security decision is required, the policy enforcement code passes a pair of SIDs (typically the SID of a subject and the SID of an object, but sometimes a pair of subject SIDs or a pair of object SIDs), and an object security class to the security server. The object security class indicates the kind of object, e.g. a process, a regular file, a directory, a TCP socket, etc.

.IP "" 8

Access decisions specify whether or not a permission is granted for a given pair of SIDs and class. Each object class has a set of associated permissions defined to control operations on objects with that class.

.PP

D\ -Bus performs SELinux security checks in two places.

.PP

First, any time a message is routed from one connection to another connection, the bus daemon will check permissions with the security context of the first connection as source, security context of the second connection as target, object class "dbus" and requested permission "send_msg".

.PP

If a security context is not available for a connection (impossible when using UNIX domain sockets), then the target context used is the context of the bus daemon itself. There is currently no way to change this default, because we're assuming that only UNIX domain sockets will be used to connect to the systemwide bus. If this changes, we'll probably add a way to set the default connection context.

.PP

Second, any time a connection asks to own a name, the bus daemon will check permissions with the security context of the connection as source, the security context specified for the name in the config file as target, object class "dbus" and requested permission "acquire_svc".

.PP

The security context for a bus name is specified with the <associate> element described earlier in this document. If a name has no security context associated in the configuration file, the security context of the bus daemon itself will be used.

.SH DEBUGGING

.PP

If you're trying to figure out where your messages are going or why you aren't getting messages, there are several things you can try.

.PP

Remember that the system bus is heavily locked down and if you haven't installed a security policy file to allow your message through, it won't work. For the session bus, this is not a concern.

.PP

The simplest way to figure out what's happening on the bus is to run the `\fIdbus\-monitor\` program, which comes with the `D\Bus` package. You can also send test messages with `\fIdbus\-send\`. These programs have their own man pages.

.PP

If you want to know what the daemon itself is doing, you might consider running a separate copy of the daemon to test against. This will allow you to put the daemon under a debugger, or run it with verbose output, without messing up your real session and system daemons.

.PP

To run a separate test copy of the daemon, for example you might open a terminal and type:

.nf

```
DBUS_VERBOSE=1 dbus\-daemon \-\-session \-\-print\-address
```

.fi

.PP

The test daemon address will be printed when the daemon starts. You will need to copy\and\paste this address and use it as the value of the `DBUS_SESSION_BUS_ADDRESS` environment variable when you launch the applications you want to test. This will cause those applications to connect to your test bus instead of the `DBUS_SESSION_BUS_ADDRESS` of your real session bus.

.PP

DBUS_VERBOSE=1 will have NO EFFECT unless your copy of D\Bus was compiled with verbose mode enabled. This is not recommended in production builds due to performance impact. You may need to rebuild D\Bus if your copy was not built with debugging in mind.

(DBUS_VERBOSE

also affects the D\Bus library and thus applications using D\Bus; it may

be useful to see verbose output on both the client side and from the daemon.)

.PP

If you want to get fancy, you can create a custom bus configuration for your test bus (see the session.conf and system.conf files that define the two default configurations for example). This would allow you to specify a different directory for .service files, for example.

.SH NAME

dbus\daemon \- Message bus daemon

.SH SYNOPSIS

.PP

.B dbus\daemon

dbus\daemon [\-\-version] [\-\-session] [\-\-system] [\-\-config\-

file=FILE]

[\-\-print\-address[=DESCRIPTOR]] [\-\-print\-pid[=DESCRIPTOR]] [\-\-

fork]

.SH DESCRIPTION

\fIdbus\daemon\fP is the D\Bus message bus daemon. See <http://www.freedesktop.org/software/dbus/> for more information about the big picture. D\Bus is first a library that provides one-to-one communication between any two applications; \fIdbus\daemon\fP is an application that uses this library to implement a message bus daemon. Multiple programs connect to the message bus daemon and can exchange messages with one another.

.PP

There are two standard message bus instances: the systemwide message bus

(installed on many systems as the "messagebus" init service) and the per\user\login\session message bus (started each time a user logs in).

\fIdbus\daemon\fp is used for both of these instances, but with a different configuration file.

.PP

The \-\-session option is equivalent to

"\-\-config\file=@EXPANDED_SYSCONFDIR@/dbus\-1/session.conf" and the \-\-system

option is equivalent to

"\-\-config\file=@EXPANDED_SYSCONFDIR@/dbus\-1/system.conf". By creating

additional configuration files and using the \-\-config\file option, additional special\purpose message bus daemons could be created.

.PP

The systemwide daemon is normally launched by an init script, standardly called simply "messagebus".

.PP

The systemwide daemon is largely used for broadcasting system events, such as changes to the printer queue, or adding/removing devices.

.PP

The per\session daemon is used for various interprocess communication among desktop applications (however, it is not tied to X or the GUI in any way).

.PP

SIGHUP will cause the D\Bus daemon to PARTIALLY reload its configuration file and to flush its user/group information caches.

Some

configuration changes would require kicking all apps off the bus; so they will

only take effect if you restart the daemon. Policy changes should take effect

with SIGHUP.

.SH OPTIONS

The following options are supported:

.TP

.I "\-\-config\file=FILE"

Use the given configuration file.

.TP

.I "\-\-fork"

Force the message bus to fork and become a daemon, even if the configuration file does not specify that it should.

In most contexts the configuration file already gets this right, though.

.I "\-\-nofork"

Force the message bus not to fork and become a daemon, even if the configuration file specifies that it should.

.TP

.I "\-\-print\address[=DESCRIPTOR]"

Print the address of the message bus to standard output, or to the given file descriptor. This is used by programs that launch the message bus.

.TP

.I "\-\\-print\\-pid[=DESCRIPTOR]"

Print the process ID of the message bus to standard output, or to the given file descriptor. This is used by programs that launch the message bus.

.TP

.I "\-\\-session"

Use the standard configuration file for the per\\-login\\-session message bus.

.TP

.I "\-\\-system"

Use the standard configuration file for the systemwide message bus.

.TP

.I "\-\\-version"

Print the version of the daemon.

.TP

.I "\-\\-introspect"

Print the introspection information for all D\\-Bus internal interfaces.

.TP

.I "\-\\-address[=ADDRESS]"

Set the address to listen on. This option overrides the address configured in the configuration file.

.TP

.I "\-\\-systemd\\-activation"

Enable systemd\\-style service activation. Only useful in conjunction with the systemd system and session manager on Linux.

.TP

.I "\-\\-nopidfile"

Don't write a PID file even if one is configured in the configuration files.

.SH CONFIGURATION FILE

A message bus daemon has a configuration file that specializes it for a particular application. For example, one configuration file might set up the message bus to be a systemwide message bus, while another might set it up to be a per\\-user\\-login\\-session bus.

.PP

The configuration file also establishes resource limits, security parameters, and so forth.

.PP

The configuration file is not part of any interoperability specification and its backward compatibility is not guaranteed; this document is documentation, not specification.

.PP

The standard systemwide and per\\-session message bus setups are

configured in the files "@EXPANDED_SYSCONFDIR@/dbus\-1/system.conf" and "@EXPANDED_SYSCONFDIR@/dbus\-1/session.conf". These files normally <include> a system\local.conf or session\local.conf; you can put local overrides in those files to avoid modifying the primary configuration files.

.PP

The configuration file is an XML document. It must have the following doctype declaration:

.nf

```
<!DOCTYPE busconfig PUBLIC "-//freedesktop//DTD D\Bus Bus
Configuration 1.0//EN"
"http://www.freedesktop.org/standards/dbus/1.0/busconfig.dtd">
```

.fi

.PP

The following elements may be present in the configuration file.

.TP

.I "<busconfig>"

.PP

Root element.

.TP

.I "<type>"

.PP

The well-known type of the message bus. Currently known values are "system" and "session"; if other values are set, they should be either added to the D\Bus specification, or namespaced. The last <type> element "wins" (previous values are ignored). This element only controls which message bus specific environment variables are set in activated clients. Most of the policy that distinguishes a session bus from the system bus is controlled from the other elements in the configuration file.

.PP

If the well-known type of the message bus is "session", then the DBUS_STARTER_BUS_TYPE environment variable will be set to "session" and the DBUS_SESSION_BUS_ADDRESS environment variable will be set to the address of the session bus. Likewise, if the type of the message bus is "system", then the DBUS_STARTER_BUS_TYPE environment variable will be set to "system" and the DBUS_SESSION_BUS_ADDRESS environment variable will be set to the address of the system bus (which is normally well known anyway).

.PP

Example: <type>session</type>

.TP
.I "<include>"

.PP
Include a file <include>filename.conf</include> at this point. If the filename is relative, it is located relative to the configuration file doing the including.

.PP
<include> has an optional attribute "ignore_missing=(yes|no)" which defaults to "no" if not provided. This attribute controls whether it's a fatal error for the included file to be absent.

.TP
.I "<includedir>"

.PP
Include all files in <includedir>foo.d</includedir> at this point. Files in the directory are included in undefined order. Only files ending in ".conf" are included.

.PP
This is intended to allow extension of the system bus by particular packages. For example, if CUPS wants to be able to send out notification of printer queue changes, it could install a file to @EXPANDED_SYSCONFDIR@/dbus\-1/system.d that allowed all apps to receive this message and allowed the printer daemon user to send it.

.TP
.I "<user>"

.PP
The user account the daemon should run as, as either a username or a UID. If the daemon cannot change to this UID on startup, it will exit. If this element is not present, the daemon will not change or care about its UID.

.PP
The last <user> entry in the file "wins", the others are ignored.

.PP
The user is changed after the bus has completed initialization. So sockets etc. will be created before changing user, but no data will be read from clients before changing user. This means that sockets and PID files can be created in a location that requires root privileges for writing.

.TP

.I "<fork>"

.PP

If present, the bus daemon becomes a real daemon (forks into the background, etc.). This is generally used rather than the `--fork` command line option.

.TP

.I "<keep_umask>"

.PP

If present, the bus daemon keeps its original umask when forking. This may be useful to avoid affecting the behavior of child processes.

.TP

.I "<listen>"

.PP

Add an address that the bus should listen on. The address is in the standard D\ -Bus format that contains a transport name plus possible parameters/options.

.PP

Example: `<listen>unix:path=/tmp/foo</listen>`

.PP

Example: `<listen>tcp:host=localhost,port=1234</listen>`

.PP

If there are multiple `<listen>` elements, then the bus listens on multiple addresses. The bus will pass its address to started services or other interested parties with the last address given in `<listen>` first. That is, apps will try to connect to the last `<listen>` address first.

.PP

tcp sockets can accept IPv4 addresses, IPv6 addresses or hostnames. If a hostname resolves to multiple addresses, the server will bind to all of them. The `family=ipv4` or `family=ipv6` options can be used to force it to bind to a subset of addresses

.PP

Example: `<listen>tcp:host=localhost,port=0,family=ipv4</listen>`

.PP

A special case is using a port number of zero (or omitting the port), which means to choose an available port selected by the operating system. The port number chosen can be obtained with the `--print-address` command line parameter and will be present in other cases where the server reports its own address, such as when `DBUS_SESSION_BUS_ADDRESS` is set.

.PP

Example: <listen>tcp:host=localhost,port=0</listen>

.PP

tcp addresses also allow a bind=hostname option, which will override the host option specifying what address to bind to, without changing the address reported by the bus. The bind option can also take a special name '*' to cause the bus to listen on all local address (INADDR_ANY). The specified host should be a valid name of the local machine or weird stuff will happen.

.PP

Example: <listen>tcp:host=localhost,bind=*,port=0</listen>

.TP

.I "<auth>"

.PP

Lists permitted authorization mechanisms. If this element doesn't exist, then all known mechanisms are allowed. If there are multiple <auth> elements, all the listed mechanisms are allowed. The order in which mechanisms are listed is not meaningful.

.PP

Example: <auth>EXTERNAL</auth>

.PP

Example: <auth>DBUS_COOKIE_SHA1</auth>

.TP

.I "<servicedir>"

.PP

Adds a directory to scan for .service files. Directories are scanned starting with the last to appear in the config file (the first .service file found that provides a particular service will be used).

.PP

Service files tell the bus how to automatically start a program. They are primarily used with the per\ -user\ -session bus, not the systemwide bus.

.TP

.I "<standard_session_servicedirs/>"

.PP

<standard_session_servicedirs/> is equivalent to specifying a series of <servicedir/> elements for each of the data directories in the "XDG Base Directory Specification" with the subdirectory "dbus\ -1/services", so for example "/usr/share/dbus\ -1/services" would be among the

directories searched.

.PP

The "XDG Base Directory Specification" can be found at <http://freedesktop.org/wiki/Standards/basedir\spec> if it hasn't moved, otherwise try your favorite search engine.

.PP

The `<standard_session_servicedirs/>` option is only relevant to the `per\user\session` bus daemon defined in `@EXPANDED_SYSCONFDIR@/dbus\1/session.conf`. Putting it in any other configuration file would probably be nonsense.

.TP

.I "<standard_system_servicedirs/>"

.PP

`<standard_system_servicedirs/>` specifies the standard system-wide activation directories that should be searched for service files. This option defaults to `@EXPANDED_DATADIR@/dbus\1/system\services`.

.PP

The `<standard_system_servicedirs/>` option is only relevant to the `per\system` bus daemon defined in `@EXPANDED_SYSCONFDIR@/dbus\1/system.conf`. Putting it in any other configuration file would probably be nonsense.

.TP

.I "<servicehelper/>"

.PP

`<servicehelper/>` specifies the setuid helper that is used to launch system daemons with an alternate user. Typically this should be the `dbus\daemon\launch\helper` executable in located in `libexec`.

.PP

The `<servicehelper/>` option is only relevant to the `per\system` bus daemon defined in `@EXPANDED_SYSCONFDIR@/dbus\1/system.conf`. Putting it in any other configuration file would probably be nonsense.

.TP

.I "<limit>"

.PP

`<limit>` establishes a resource limit. For example:

.nf

 <limit name="max_message_size">64</limit>

 <limit name="max_completed_connections">512</limit>

.fi

.PP

The name attribute is mandatory.
Available limit names are:

```
.nf
    "max_incoming_bytes"      : total size in bytes of messages
                              incoming from a single connection
    "max_incoming_unix_fds"  : total number of unix fds of
messages
                              incoming from a single connection
    "max_outgoing_bytes"     : total size in bytes of messages
                              queued up for a single connection
    "max_outgoing_unix_fds"  : total number of unix fds of
messages
                              queued up for a single connection
    "max_message_size"       : max size of a single message in
                              bytes
    "max_message_unix_fds"   : max unix fds of a single message
    "service_start_timeout"   : milliseconds (thousandths) until
                              a started service has to connect
    "auth_timeout"           : milliseconds (thousandths) a
                              connection is given to
                              authenticate
    "max_completed_connections" : max number of authenticated
connections
    "max_incomplete_connections" : max number of unauthenticated
                              connections
    "max_connections_per_user" : max number of completed
connections from
                              the same user
    "max_pending_service_starts" : max number of service launches in
                              progress at the same time
    "max_names_per_connection" : max number of names a single
                              connection can own
    "max_match_rules_per_connection": max number of match rules for
a single
                              connection
    "max_replies_per_connection" : max number of pending method
                              replies per connection
                              (number of calls\ -in\ -progress)
    "reply_timeout"           : milliseconds (thousandths)
                              until a method call times out
.fi
```

.PP

The max incoming/outgoing queue sizes allow a new message to be queued if one byte remains below the max. So you can in fact exceed the max by max_message_size.

.PP

max_completed_connections divided by max_connections_per_user is the

number of users that can work together to denial\of\service all other users by using up all connections on the systemwide bus.

.PP

Limits are normally only of interest on the systemwide bus, not the user session buses.

.TP

.I "<policy>"

.PP

The <policy> element defines a security policy to be applied to a particular set of connections to the bus. A policy is made up of <allow> and <deny> elements. Policies are normally used with the systemwide bus; they are analogous to a firewall in that they allow expected traffic and prevent unexpected traffic.

.PP

Currently, the system bus has a default\deny policy for sending method calls and owning bus names. Everything else, in particular reply messages, receive checks, and signals has a default allow policy.

.PP

In general, it is best to keep system services as small, targeted programs which run in their own process and provide a single bus name. Then, all that is needed is an <allow> rule for the "own" permission to let the process claim the bus name, and a "send_destination" rule to allow traffic from some or all uids to your service.

.PP

The <policy> element has one of four attributes:

.nf

```
context="(default|mandatory)"
at_console="(true|false)"
user="username or userid"
group="group name or gid"
```

.fi

.PP

Policies are applied to a connection as follows:

.nf

```
\- all context="default" policies are applied
```

```
\- all group="connection's user's group" policies are applied
   in undefined order
\- all user="connection's auth user" policies are applied
   in undefined order
\- all at_console="true" policies are applied
\- all at_console="false" policies are applied
\- all context="mandatory" policies are applied
.fi
```

.PP

Policies applied later will override those applied earlier, when the policies overlap. Multiple policies with the same user/group/context are applied in the order they appear in the config file.

.TP

```
.I "<deny>"
.I "<allow>"
```

.PP

A <deny> element appears below a <policy> element and prohibits some action. The <allow> element makes an exception to previous <deny> statements, and works just like <deny> but with the inverse meaning.

.PP

The possible attributes of these elements are:
.nf

```
send_interface="interface_name"
send_member="method_or_signal_name"
send_error="error_name"
send_destination="name"
send_type="method_call" | "method_return" | "signal" | "error"
send_path="/path/name"

receive_interface="interface_name"
receive_member="method_or_signal_name"
receive_error="error_name"
receive_sender="name"
receive_type="method_call" | "method_return" | "signal" | "error"
receive_path="/path/name"

send_requested_reply="true" | "false"
receive_requested_reply="true" | "false"

eavesdrop="true" | "false"

own="name"
own_prefix="name"
user="username"
group="groupname"
```

.fi

.PP

Examples:

.nf

```
<deny send_destination="org.freedesktop.Service"
send_interface="org.freedesktop.System" send_member="Reboot"/>
<deny send_destination="org.freedesktop.System"/>
<deny receive_sender="org.freedesktop.System"/>
<deny user="john"/>
<deny group="enemies"/>
```

.fi

.PP

The `<deny>` element's attributes determine whether the deny "matches" a particular action. If it matches, the action is denied (unless later rules in the config file allow it).

.PP

`send_destination` and `receive_sender` rules mean that messages may not be sent to or received from the *owner* of the given name, not that they may not be sent *to that name*. That is, if a connection owns services A, B, C, and sending to A is denied, sending to B or C will not work either.

.PP

The other `send_*` and `receive_*` attributes are purely textual/`by\`-value matches against the given field in the message header.

.PP

"Eavesdropping" occurs when an application receives a message that was explicitly addressed to a name the application does not own, or is a reply to such a message. Eavesdropping thus only applies to messages that are addressed to services and replies to such messages (i.e. it does not apply to signals).

.PP

For `<allow>`, `eavesdrop="true"` indicates that the rule matches even when eavesdropping. `eavesdrop="false"` is the default and means that the rule only allows messages to go to their specified recipient. For `<deny>`, `eavesdrop="true"` indicates that the rule matches only when eavesdropping. `eavesdrop="false"` is the default for `<deny>` also, but here it means that the rule applies always, even when not eavesdropping. The `eavesdrop` attribute can only be combined with `send` and `receive` rules (with `send_*` and `receive_*` attributes).

.PP

The `[send|receive]_requested_reply` attribute works similarly to the `eavesdrop` attribute. It controls whether the `<deny>` or `<allow>` matches a reply that is expected (corresponds to a previous method call message). This attribute only makes sense for reply messages (errors and method returns), and is ignored for other message types.

.PP

For `<allow>`, `[send|receive]_requested_reply="true"` is the default and indicates that only requested replies are allowed by the

rule. [send|receive]_requested_reply="false" means that the rule allows any reply even if unexpected.

.PP

For <deny>, [send|receive]_requested_reply="false" is the default but indicates that the rule matches only when the reply was not requested. [send|receive]_requested_reply="true" indicates that the rule applies always, regardless of pending reply state.

.PP

user and group denials mean that the given user or group may not connect to the message bus.

.PP

For "name", "username", "groupname", etc. the character "*" can be substituted, meaning "any." Complex globs like "foo.bar.*" aren't allowed for now because they'd be work to implement and maybe encourage sloppy security anyway.

.PP

<allow own_prefix="a.b"/> allows you to own the name "a.b" or any name whose first dot-separated elements are "a.b": in particular, you can own "a.b.c" or "a.b.c.d", but not "a.bc" or "a.c". This is useful when services like Telepathy and ReserveDevice define a meaning for subtrees of well-known names, such as org.freedesktop.Telepathy.ConnectionManager.(anything) and org.freedesktop.ReserveDevice1.(anything).

.PP

It does not make sense to deny a user or group inside a <policy> for a user or group; user/group denials can only be inside context="default" or context="mandatory" policies.

.PP

A single <deny> rule may specify combinations of attributes such as send_destination and send_interface and send_type. In this case, the denial applies only if both attributes match the message being denied. e.g. <deny send_interface="foo.bar" send_destination="foo.blah"/> would deny messages with the given interface AND the given bus name. To get an OR effect you specify multiple <deny> rules.

.PP

You can't include both send_ and receive_ attributes on the same rule, since "whether the message can be sent" and "whether it can be received" are evaluated separately.

.PP

Be careful with send_interface/receive_interface, because the

interface field in messages is optional. In particular, do NOT specify `<deny send_interface="org.foo.Bar"/>`! This will cause no\-interface messages to be blocked for all services, which is almost certainly not what you intended. Always use rules of the form: `<deny send_interface="org.foo.Bar" send_destination="org.foo.Service"/>`

.TP
.I "<selinux>"

.PP
The `<selinux>` element contains settings related to Security Enhanced Linux.
More details below.

.TP
.I "<associate>"

.PP
An `<associate>` element appears below an `<selinux>` element and creates a mapping. Right now only one kind of association is possible:
.nf
 `<associate own="org.freedesktop.Foobar" context="foo_t"/>`
.fi

.PP
This means that if a connection asks to own the name "org.freedesktop.Foobar" then the source context will be the context of the connection and the target context will be "foo_t" \- see the short discussion of SELinux below.

.PP
Note, the context here is the target context when requesting a name, NOT the context of the connection owning the name.

.PP
There's currently no way to set a default for owning any name, if we add this syntax it will look like:
.nf
 `<associate own="*" context="foo_t"/>`
.fi
If you find a reason this is useful, let the developers know. Right now the default will be the security context of the bus itself.

.PP
If two `<associate>` elements specify the same name, the element appearing later in the configuration file will be used.

.SH SELinux

.PP

See <http://www.nsa.gov/selinux/> for full details on SELinux. Some useful excerpts:

.IP "" 8

Every subject (process) and object (e.g. file, socket, IPC object, etc) in the system is assigned a collection of security attributes, known as a security context. A security context contains all of the security attributes associated with a particular subject or object that are relevant to the security policy.

.IP "" 8

In order to better encapsulate security contexts and to provide greater efficiency, the policy enforcement code of SELinux typically handles security identifiers (SIDs) rather than security contexts. A SID is an integer that is mapped by the security server to a security context at runtime.

.IP "" 8

When a security decision is required, the policy enforcement code passes a pair of SIDs (typically the SID of a subject and the SID of an object, but sometimes a pair of subject SIDs or a pair of object SIDs), and an object security class to the security server. The object security class indicates the kind of object, e.g. a process, a regular file, a directory, a TCP socket, etc.

.IP "" 8

Access decisions specify whether or not a permission is granted for a given pair of SIDs and class. Each object class has a set of associated permissions defined to control operations on objects with that class.

.PP

D\ -Bus performs SELinux security checks in two places.

.PP

First, any time a message is routed from one connection to another connection, the bus daemon will check permissions with the security context of the first connection as source, security context of the second connection as target, object class "dbus" and requested permission "send_msg".

.PP

If a security context is not available for a connection (impossible when using UNIX domain sockets), then the target context used is the context of the bus daemon itself. There is currently no way to change this default, because we're assuming that only UNIX domain sockets will be used to connect to the systemwide bus. If this changes, we'll probably add a way to set the default connection context.

.PP

Second, any time a connection asks to own a name, the bus daemon will check permissions with the security context of the connection as source, the security context specified for the name in the config file as target, object class "dbus" and requested permission "acquire_svc".

.PP

The security context for a bus name is specified with the <associate> element described earlier in this document. If a name has no security context associated in the configuration file, the security context of the bus daemon itself will be used.

.SH DEBUGGING

.PP

If you're trying to figure out where your messages are going or why you aren't getting messages, there are several things you can try.

.PP

Remember that the system bus is heavily locked down and if you haven't installed a security policy file to allow your message through, it won't work. For the session bus, this is not a concern.

.PP

The simplest way to figure out what's happening on the bus is to run the `\fIdbus\monitor` program, which comes with the `D-Bus` package. You can also send test messages with `\fIdbus\send`. These programs have their own man pages.

.PP

If you want to know what the daemon itself is doing, you might consider running a separate copy of the daemon to test against. This will allow you to put the daemon under a debugger, or run it with verbose output, without messing up your real session and system daemons.

.PP

To run a separate test copy of the daemon, for example you might open a terminal and type:

.nf

```
DBUS_VERBOSE=1 dbus\daemon \-\-session \-\-print\-\-address
```

.fi

.PP

The test daemon address will be printed when the daemon starts. You will need to copy\and\paste this address and use it as the value of the `DBUS_SESSION_BUS_ADDRESS` environment variable when you launch the applications you want to test. This will cause those applications to connect to your test bus instead of the `DBUS_SESSION_BUS_ADDRESS` of your real session bus.

.PP

DBUS_VERBOSE=1 will have NO EFFECT unless your copy of D\Bus was compiled with verbose mode enabled. This is not recommended in production builds due to performance impact. You may need to rebuild D\Bus if your copy was not built with debugging in mind.

(DBUS_VERBOSE

also affects the D\Bus library and thus applications using D\Bus; it may

be useful to see verbose output on both the client side and from the daemon.)

.PP

If you want to get fancy, you can create a custom bus configuration for your test bus (see the session.conf and system.conf files that define the two default configurations for example). This would allow you to specify a different directory for .service files, for example.

<refsect1 id='description'><title>DESCRIPTION</title>
<para><command>dbus-daemon</command> is the D-Bus message bus daemon.
See
<ulink
url='http://www.freedesktop.org/software/dbus/'>http://www.freedesktop
.org/software/dbus/</ulink> for more information about
the big picture. D-Bus is first a library that provides one-to-one
communication between any two applications; <command>dbus-
daemon</command> is an
application that uses this library to implement a message bus
daemon. Multiple programs connect to the message bus daemon and can
exchange messages with one another.</para>

<para>There are two standard message bus instances: the systemwide
message bus
(installed on many systems as the "messagebus" init service) and the
per-user-login-session message bus (started each time a user logs in).
<command>dbus-daemon</command> is used for both of these instances,
but with
a different configuration file.</para>

<para>The --session option is equivalent to
"--config-file=/etc/dbus-1/session.conf" and the --system
option is equivalent to
"--config-file=/etc/dbus-1/system.conf". By creating
additional configuration files and using the --config-file option,
additional special-purpose message bus daemons could be
created.</para>

<para>The systemwide daemon is normally launched by an init script,
standardly called simply "messagebus".</para>

<para>The systemwide daemon is largely used for broadcasting system
events,

such as changes to the printer queue, or adding/removing devices.</para>

<para>The per-session daemon is used for various interprocess communication among desktop applications (however, it is not tied to X or the GUI in any way).</para>

<para>SIGHUP will cause the D-Bus daemon to PARTIALLY reload its configuration file and to flush its user/group information caches. Some configuration changes would require kicking all apps off the bus; so they will only take effect if you restart the daemon. Policy changes should take effect with SIGHUP.</para>

</refsect1>

</varlistentry>
</variablelist>
</refsect1>

<refsect1 id='configuration_file'><title>CONFIGURATION FILE</title>
<para>A message bus daemon has a configuration file that specializes
it
for a particular application. For example, one configuration
file might set up the message bus to be a systemwide message bus,
while another might set it up to be a per-user-login-session
bus.</para>

<para>The configuration file also establishes resource limits,
security
parameters, and so forth.</para>

<para>The configuration file is not part of any interoperability
specification and its backward compatibility is not guaranteed; this
document is documentation, not specification.</para>

<para>The standard systemwide and per-session message bus setups are
configured in the files "/etc/dbus-1/system.conf" and
"/etc/dbus-1/session.conf". These files normally
<include> a system-local.conf or session-local.conf; you can put
local

overrides in those files to avoid modifying the primary configuration files.</para>

<para>The configuration file is an XML document. It must have the following

doctype declaration:</para>

```
<literallayout remap='.nf'>
```

```
    &lt;!DOCTYPE busconfig PUBLIC "-//freedesktop//DTD D-Bus Bus Configuration 1.0//EN"
```

```
    "<ulink

```

<para>A <deny> element appears below a <policy> element and prohibits some action. The <allow> element makes an exception to previous <deny> statements, and works just like <deny> but with the inverse meaning.</para>

<para>The possible attributes of these elements are:</para>

```
<literallayout remap='.nf'>
  send_interface="interface_name"
  send_member="method_or_signal_name"
  send_error="error_name"
  send_destination="name"
  send_type="method_call" | "method_return" | "signal" | "error"
  send_path="/path/name"

  receive_interface="interface_name"
  receive_member="method_or_signal_name"
  receive_error="error_name"
  receive_sender="name"
  receive_type="method_call" | "method_return" | "signal" | "error"
  receive_path="/path/name"

  send_requested_reply="true" | "false"
  receive_requested_reply="true" | "false"

  eavesdrop="true" | "false"

  own="name"
  own_prefix="name"
  user="username"
  group="groupname"
</literallayout> <!-- .fi -->
```

<para>Examples:</para>

```
<literallayout remap='.nf'>
  <deny send_interface="org.freedesktop.System"
send_member="Reboot"/>
  <deny receive_interface="org.freedesktop.System"
receive_member="Reboot"/>
  <deny own="org.freedesktop.System"/>
  <deny send_destination="org.freedesktop.System"/>
  <deny receive_sender="org.freedesktop.System"/>
  <deny user="john"/>
  <deny group="enemies"/>
</literallayout> <!-- .fi -->
```

<para>The <deny> element's attributes determine whether the deny "matches" a

particular action. If it matches, the action is denied (unless later rules in the config file allow it).</para>

<para>send_destination and receive_sender rules mean that messages may not be sent to or received from the *owner* of the given name, not that they may not be sent *to that name*. That is, if a connection owns services A, B, C, and sending to A is denied, sending to B or C will not work either.</para>

<para>The other send_* and receive_* attributes are purely textual/by-value matches against the given field in the message header.</para>

<para>"Eavesdropping" occurs when an application receives a message that was explicitly addressed to a name the application does not own. Eavesdropping thus only applies to messages that are addressed to services (i.e. it does not apply to signals).</para>

<para>For <code><allow></code>, eavesdrop="true" indicates that the rule matches even when eavesdropping. eavesdrop="false" is the default and means that the rule only allows messages to go to their specified recipient. For <code><deny></code>, eavesdrop="true" indicates that the rule matches only when eavesdropping. eavesdrop="false" is the default for <code><deny></code> also, but here it means that the rule applies always, even when not eavesdropping. The eavesdrop attribute can only be combined with receive rules (with receive_* attributes).</para>

<para>The [send|receive]_requested_reply attribute works similarly to the eavesdrop attribute. It controls whether the <code><deny></code> or <code><allow></code> matches a reply that is expected (corresponds to a previous method call message). This attribute only makes sense for reply messages (errors and method returns), and is ignored for other message types.</para>

<para>For <code><allow></code>, [send|receive]_requested_reply="true" is the default and indicates that only requested replies are allowed by the rule. [send|receive]_requested_reply="false" means that the rule allows any reply even if unexpected.</para>

<para>For <code><deny></code>, [send|receive]_requested_reply="false" is the default but indicates that the rule matches only when the reply was not requested. [send|receive]_requested_reply="true" indicates that the rule applies always, regardless of pending reply state.</para>

<para>user and group denials mean that the given user or group may not connect to the message bus.</para>

<para>For "name", "username", "groupname", etc. the character "*" can be substituted, meaning "any." Complex globs like "foo.bar.*" aren't allowed for now because they'd be work to implement and maybe encourage sloppy security anyway.</para>

<para><code><allow own_prefix="a.b"/></code> allows you to own the name "a.b" or any name whose first dot-separated elements are "a.b": in particular, you can own "a.b.c" or "a.b.c.d", but not "a.bc" or "a.c". This is useful when services like Telepathy and ReserveDevice define a meaning for subtrees of well-known names, such as org.freedesktop.Telepathy.ConnectionManager.(anything) and org.freedesktop.ReserveDevice1.(anything).</para>

<para>It does not make sense to deny a user or group inside a <code><policy></code> for a user or group; user/group denials can only be inside context="default" or context="mandatory" policies.</para>

<para>A single <code><deny></code> rule may specify combinations of attributes such as send_destination and send_interface and send_type. In this case, the denial applies only if both attributes match the message being denied. e.g. <code><deny send_interface="foo.bar" send_destination="foo.blah"/></code> would deny messages with the given interface AND the given bus name. To get an OR effect you specify multiple <code><deny></code> rules.</para>

<para>You can't include both send_ and receive_ attributes on the same rule, since "whether the message can be sent" and "whether it can be received" are evaluated separately.</para>

<para>Be careful with send_interface/receive_interface, because the interface field in messages is optional.</para>

</literallayout> <!-- .fi -->
```

<para>If you find a reason this is useful, let the developers know.

Right now the default will be the security context of the bus itself.</para>

<para>If two <code><lt;associate></code> elements specify the same name, the element appearing later in the configuration file will be used.</para>

</refsect1>

<refsect1 id='selinux'><title>SELinux</title>

<para>See <ulink url='http://www.nsa.gov/selinux/'>http://www.nsa.gov/selinux/</ulink> for full details on SELinux. Some useful excerpts:</para>

<para>Every subject (process) and object (e.g. file, socket, IPC object, etc) in the system is assigned a collection of security attributes, known as a security context. A security context contains all of the security attributes associated with a particular subject or object that are relevant to the security policy.</para>

<para>In order to better encapsulate security contexts and to provide greater efficiency, the policy enforcement code of SELinux typically handles security identifiers (SIDs) rather than security contexts. A SID is an integer that is mapped by the security server to a security context at runtime.</para>

<para>When a security decision is required, the policy enforcement code passes a pair of SIDs (typically the SID of a subject and the SID of an object, but sometimes a pair of subject SIDs or a pair of object SIDs), and an object security class to the security server. The object security class indicates the kind of object, e.g. a process, a regular file, a directory, a TCP socket, etc.</para>

<para>Access decisions specify whether or not a permission is granted for a given pair of SIDs and class. Each object class has a set of associated permissions defined to control operations on objects with that class.</para>

<para>D-Bus performs SELinux security checks in two places.</para>

<para>First, any time a message is routed from one connection to another

connection, the bus daemon will check permissions with the security context of the first connection as source, security context of the second connection as target, object class "dbus" and requested permission "send_msg".</para>

<para>If a security context is not available for a connection (impossible when using UNIX domain sockets), then the target context used is the context of the bus daemon itself. There is currently no way to change this default, because we're assuming that only UNIX domain sockets will be used to connect to the systemwide bus. If this changes, we'll probably add a way to set the default connection context.</para>

<para>Second, any time a connection asks to own a name, the bus daemon will check permissions with the security context of the connection as source, the security context specified for the name in the config file as target, object class "dbus" and requested permission "acquire_svc".</para>

<para>The security context for a bus name is specified with the <associate> element described earlier in this document. If a name has no security context associated in the configuration file, the security context of the bus daemon itself will be used.</para>

/** @} */ /* End of internals */

/**
 * @defgroup DBusErrors Error reporting
 * @ingroup DBus
 * @brief Error reporting
 *
 * Types and functions related to reporting errors.
 *
 * In essence D-Bus error reporting works as follows:
 *
 * @code
 * DBusError error;
 * dbus_error_init (&error);
 * dbus_some_function (arg1, arg2, &error);
 * if (dbus_error_is_set (&error))
 * {
 *     fprintf (stderr, "an error occurred: %s\n", error.message);
 *     dbus_error_free (&error);
 * }
 * @endcode
 *
 * By convention, all functions allow #NULL instead of a DBusError*,
 * so callers who don't care about the error can ignore it.
 *
 * There are some rules. An error passed to a D-Bus function must
 * always be unset; you can't pass in an error that's already set. If
 * a function has a return code indicating whether an error occurred,
 * and also a #DBusError parameter, then the error will always be set
 * if and only if the return code indicates an error occurred. i.e.
 * the return code and the error are never going to disagree.
 *
 * An error only needs to be freed if it's been set, not if
 * it's merely been initialized.
 *
 * You can check the specific error that occurred using
 * dbus_error_has_name().
 *
 * Errors will not be set for programming errors, such as passing
 * invalid arguments to the libdbus API. Instead, libdbus will print
 * warnings, exit on a failed assertion, or even crash in those cases
 * (in other words, incorrect use of the API results in undefined
 * behavior, possibly accompanied by helpful debugging output if
 * you're lucky).
 *
 * @{
 */

  What is D-Bus?
  </p></td></tr><tr class="answer"><td align="left"
valign="top"></td><td align="left" valign="top"><p>
  This is probably best answered by reading the D-Bus <a
class="ulink" href="dbus-tutorial.html" target="_top">tutorial</a> or
```

the introduction to the [specification](dbus-specification.html). In short, it is a system consisting of 1) a wire protocol for exposing a typical object-oriented language/framework to other applications; and 2) a bus daemon that allows applications to find and monitor one another.

Phrased differently, D-Bus is 1) an interprocess communication (IPC) system and 2) some higher-level structure (lifecycle tracking, service activation, security policy) provided by two bus daemons, one systemwide and one per-user-session.

2.

Is D-Bus stable/finished?

The low-level library "libdbus" and the protocol specification are considered

ABI stable. The <README>

file has a discussion of the API/ABI stability guarantees. Higher-level bindings (such as those for Qt, GLib, Python, Java, C#) each have their own release schedules and degree of maturity, not linked to the low-level library and bus daemon release. Check the project page for the binding you're considering to understand that project's policies.

3.

How is the reference implementation licensed? Can I use it in proprietary applications?

The short answer is yes, you can use it in proprietary applications.

You should read the <COPYING>

file, which offers you the choice of two licenses. These are the GPL and the

AFL. The GPL requires that your application be licensed under the GPL

as well. The AFL is an "X-style" or "BSD-style" license compatible

with proprietary licensing, but it does have some requirements; in particular it prohibits you from filing a lawsuit alleging that the D-Bus software infringes your patents while you continue to use D-Bus. If you're going to sue, you have to stop using the software. Read the licenses to determine their meaning, this FAQ entry is not intended to change the meaning or terms of the licenses.

</p></td></tr><tr class="question" title="4."><td align="left" valign="top"><p>4.</p></td><td align="left" valign="top"><p>

What is the difference between a bus name, and object path, and an interface?

</p></td></tr><tr class="answer"><td align="left" valign="top"></td><td align="left" valign="top"><p>

If you imagine a C++ program that implements a network service, then

the bus name is the hostname of the computer running this C++ program,

the object path is a C++ object instance pointer, and an interface is

a C++ class (a pure virtual or abstract class, to be exact).

</p><p>

In Java terms, the object path is an object reference, and an interface is a Java interface.

</p><p>

People get confused because if they write an application with a single object instance and a single interface, then the bus name, object path, and interface look redundant. For example, you might have a text editor that uses the bus name <code

class="literal">org.freedesktop.TextEditor</code>,</p><p>

has a global singleton object called

<code class="literal">/org/freedesktop/TextEditor</code>,</p><p>

and

that singleton object could implement the interface

<code class="literal">org.freedesktop.TextEditor</code>.</p><p>

</p><p>

However, a text editor application could as easily own multiple bus

names (for example, <code

class="literal">org.kde.KWrite</code> in addition to

generic <code class="literal">TextEditor</code>), have

multiple objects (maybe

<code class="literal">/org/kde/documents/4352</code> where

the number changes

multiple according to the document), and each object could implement multiple interfaces, such as `org.freedesktop.DBus.Introspectable`, `org.freedesktop.BasicTextField`, `org.kde.RichTextDocument`.

5. [service](#)

What is a "service"?

A service is a program that can be launched by the bus daemon to provide some functionality to other programs. Services are normally launched according to the bus name they will have.

People often misuse the word "service" for any bus name, but this tends to be ambiguous and confusing so is discouraged.

In the D-Bus docs we try to use "service" only when talking about programs the bus knows how to launch, i.e. a service always has a .service file.

6. [components](#)

Is D-Bus a "component system"?

D-Bus is not a component system. "Component system" was originally defined by COM, and was essentially a workaround for the limitations of the C++ object system (adding introspection, runtime location of objects, ABI guarantees, and so forth). With the C# language and CLR,

Microsoft added these features to the primary object system, leaving COM obsolete. Similarly, Java has much less need for something like COM than C++ did. Even QObject (from Qt) and GObject (from GLib) offer some of the same features found in COM.

Component systems are not about GUI control embedding. Embedding a spreadsheet in a word processor document is a matter of defining some specific *interfaces* that objects can implement. These interfaces provide methods related to GUI controls. So an object implementing those interfaces can be embedded.

The word "component" just means "object with some fancy features" and in modern languages all objects are effectively "components."

So components are fancy objects, and some objects are GUI controls.

A third, unrelated feature is interprocess communication or IPC. D-Bus is an IPC system. Given an object (or "component" if you must), you can expose the functionality of that object over an IPC system. Examples of IPC systems are DCOM, CORBA, SOAP, XML-RPC, and D-Bus. You can use any of these IPC systems with any object/component system, though some of them are "tuned" for specific object systems. You can think of an IPC system primarily as a wire protocol.

If you combine an IPC system with a set of GUI control interfaces, then you can have an out-of-process or dynamically-loaded GUI control.

Another related concept is the *plugin* or *extension*. Generic plugin systems such as the [Eclipse](http://eclipse.org) system are not so different from component/object systems, though perhaps a "plugin" tends to be a

bundle of objects with a user-visible name and can be downloaded/packaged as a unit.

7.

How fast is the D-Bus reference implementation?

Of course it depends a bit on what you're doing.

<http://lists.freedesktop.org/pipermail/dbus/2004-November/001779.html>

This mail contains some benchmarking. At the time of that benchmark, D-Bus one-to-one communication was about 2.5x slower than simply pushing the data raw over a socket. After the recent rewrite of the marshaling code, D-Bus is slower than that because a lot of optimization work was lost. But it can probably be sped up again.

D-Bus communication with the intermediate bus daemon should be (and as last profiled, was) about twice as slow as one-to-one mode, because a round trip involves four socket reads/writes rather than two socket reads/writes.

The overhead comes from a couple of places; part of it is "abstraction penalty" (there are layers of code to support multiple main loops, multiple transport types, security, etc.).

Probably the largest part comes from data validation (because the reference implementation does not trust incoming data).

It would be simple to add a "no validation" mode, but probably not a good idea all things considered.

Raw bandwidth isn't the only concern; D-Bus is designed to enable asynchronous communication and avoid round trips. This is frequently a more important performance issue than throughput.

8.

How large is the D-Bus reference implementation?

A production build (with assertions, unit tests, and verbose logging disabled) is on the order of a 150K shared library.

A much, much smaller implementation would be possible by omitting out of memory handling, hardcoding a main loop (or always using blocking I/O), skipping validation, and otherwise simplifying things.

9.

How does D-Bus differ from other interprocess communication or networking protocols?

Keep in mind, it is not only an IPC system; it also includes lifecycle tracking, service activation, security policy, and other higher-level structure and assumptions.

The best place to start is to read the D-Bus [tutorial](#), so you have a concrete idea what D-Bus actually is. If you understand other protocols on a wire format level, you may also want to read the D-Bus [specification](#) to see what D-Bus looks like on a low level.

As the [tutorial](#) and [specification](#) both explain, D-Bus is tuned for some specific use cases. Thus, it probably isn't tuned for what you want to do, unless you are doing the things D-Bus was designed for. Don't make the mistake of thinking that any system involving "IPC" is the same thing.

The D-Bus authors would not recommend using D-Bus for applications where it doesn't make sense. The following questions compare D-Bus to some other protocols primarily to help you understand D-Bus and decide whether it's appropriate; D-Bus is neither intended nor claimed to be the right choice for every application.

It should be possible to bridge D-Bus to other IPC systems, just as D-Bus can be bridged to object systems.

Note: the D-Bus mailing list subscribers are *very much not* interested in debating which IPC system is the One True System. So if you want to discuss that, please use another forum.

[CORBA](#) [10.](#)

How does D-Bus differ from CORBA?

Start by reading [#other-ipc](#) [9.](#)Q: 9

[CORBA](http://www.omg.org) is designed to support object-oriented IPC between objects, automatically marshalling parameters as necessary. CORBA is strongly supported by the [Open Management Group \(OMG\)](http://www.omg.org), which produces various standards and supporting documents for CORBA and has the backing of many large organizations. There are many CORBA ORBs available, both proprietary ORBs and free / open source software ORBs (the latter include [ORBit](http://orbit-resource.sourceforge.net/), [MICO](http://www.mico.org/), and [The ACE Orb \(TAO\)](http://www.theaceorb.com/)). Many organizations continue to use CORBA ORBs for various kinds of IPC.

Both GNOME and KDE have used CORBA and then moved away from it. KDE had more success with a system called DCOP, and GNOME layered a system called Bonobo on top of CORBA. Without custom extensions, CORBA does not support many of the things one wants to do in a desktop environment with the GNOME/KDE architecture.

CORBA on the other hand has a number of features of interest for enterprise and web application development, though XML systems such as SOAP are the latest fad.

</p><p>
Like D-Bus, CORBA uses a fast binary protocol (IIOP). Both systems work in terms of objects and methods, and have concepts such as "oneway" calls. Only D-Bus has direct support for "signals" as in GLib/Qt (or Java listeners, or C# delegates).

</p><p>
D-Bus hardcodes and specifies a lot of things that CORBA leaves open-ended, because CORBA is more generic and D-Bus has two specific use-cases in mind. This makes D-Bus a bit simpler.

</p><p>
However, unlike CORBA D-Bus does not specify the API for the language bindings. Instead, "native" bindings adapted specifically to the conventions of a framework such as GObject, GObject, C#, Java, Python, etc. are encouraged. The libdbus reference implementation is designed to be a backend for bindings of this nature, rather than to be used directly. The rationale is that an IPC system API should not "leak" all over a program; it should come into play only just before data goes over the wire. As an aside, OMG is apparently working on a simpler C++ binding for CORBA.

</p><p>
Many CORBA implementations such as ORBit are faster than the libdbus reference implementation. One reason is that D-Bus considers data from the other end of the connection to be untrusted and extensively validates it. But generally speaking other priorities were placed ahead of raw speed in the libdbus implementation. A fast D-Bus implementation along the lines of ORBit should be possible, of course.

</p><p>
On a more trivial note, D-Bus involves substantially fewer acronyms than CORBA.

</p></td></tr><tr class="question" title="11."><td align="left" valign="top"><p>11.</p></td><td align="left" valign="top"><p>
How does D-Bus differ from XML-RPC and SOAP?
</p></td></tr><tr class="answer"><td align="left" valign="top"></td><td align="left" valign="top"><p>
Start by reading Q: 9.
</p><p>
In SOAP and XML-RPC, RPC calls are transformed
into an XML-based format, then sent over the wire (typically using the HTTP protocol), where they are processed and returned. XML-RPC is the simple protocol (its spec is only a page or two), and SOAP is the full-featured protocol.
</p><p>
XML-RPC and SOAP impose XML parsing overhead that is normally irrelevant in the context of the Internet, but significant for constant fine-grained IPC among applications in a desktop session.
</p><p>
D-Bus offers persistent connections and with the bus daemon supports lifecycle tracking of other applications connected to the bus. With XML-RPC and SOAP, typically each method call exists in isolation and has its own HTTP connection.
</p></td></tr><tr class="question" title="12."><td align="left" valign="top"><p>12.</p></td><td align="left" valign="top"><p>
How does D-Bus differ from DCE?
</p></td></tr><tr class="answer"><td align="left" valign="top"></td><td align="left" valign="top"><p>
Start by reading Q: 9.
</p><p>
Distributed Computing Environment (DCE) is an industry-standard vendor-neutral standard that includes an IPC mechanism. The Open Group
has released an implementation as open source software.
DCE
is quite capable, and includes a vast amount of functionality such as

a distributed time service. As the name implies, DCE is intended for use in a large, multi-computer distributed application. D-Bus would

not be well-suited for this.

</p></td></tr><tr class="question" title="13."><td align="left" valign="top"><p>13.</p></td><td align="left" valign="top"><p>

How does D-Bus differ from DCOM and COM?

</p></td></tr><tr class="answer"><td align="left" valign="top"></td><td align="left" valign="top"><p>

Start by reading Q: 9.

</p><p>

Comparing D-Bus to COM is apples and oranges;

see Q: 6.

</p><p>

DCOM (distributed COM) is a Windows IPC system designed for use with

the COM object system. It's similar in some ways to DCE and CORBA.

</p></td></tr><tr class="question" title="14."><td align="left" valign="top"><p>14.</p></td><td align="left" valign="top"><p>

How does D-Bus differ from ZeroC's Internet Communications Engine (Ice)

</p></td></tr><tr class="answer"><td align="left" valign="top"></td><td align="left" valign="top"><p>

Start by reading Q: 9.

</p><p>

The Internet

Communications Engine (Ice) is a powerful IPC mechanism more

on the level of SOAP or CORBA than D-Bus. Ice has a "dual-

license" business around it; i.e. you can use it under the GPL, or pay for a

proprietary license.

</p></td></tr><tr class="question" title="15."><td align="left" valign="top"><p>15.</p></td><td align="left" valign="top"><p>

How does D-Bus differ from Inter-Client Exchange (ICE)?

</p></td></tr><tr class="answer"><td align="left" valign="top"></td><td align="left" valign="top"><p>

<a class="ulink"

href="http://www.x.org/X11R6.8.1/docs/ICE/ice.pdf" target="_top">ICE

was developed for the X Session Management protocol (XSMP), as part of the X Window System (X11R6.1). The idea was to allow desktop sessions

to contain nongraphical clients in addition to X clients.

ICE is a binary protocol designed for desktop use, and KDE's DCOP builds on ICE. ICE is substantially simpler than D-Bus (in contrast to most of the other IPC systems mentioned here, which are more complex). ICE doesn't really define a mapping to objects and methods (DCOP adds that layer). The reference implementation of ICE (libICE)

is often considered to be horrible (and horribly insecure).

DCOP and XSMP are the only two widely-used applications of ICE, and both could in principle be replaced by D-Bus. (Though whether

GNOME and KDE will bother is an open question.)

[16.](#)

How does D-Bus differ from DCOP?

Start by reading [Q: 9](#).

D-Bus is intentionally pretty similar to [DCOP](#),

and can be thought of as a "DCOP the next generation" suitable for

sharing between the various open source desktop projects.

D-Bus is a bit more complex than DCOP, though the Qt binding for D-Bus

should not be more complex for programmers. The additional complexity

of D-Bus arises from its separation of object references vs. bus names

vs. interfaces as distinct concepts, and its support for one-to-one

connections in addition to connections over the bus. The libdbus

reference implementation has a lot of API to support multiple bindings

and main loops, and performs data validation and out-of-memory handling

in order to support secure applications such as the systemwide bus.

</p><p>

D-Bus is probably somewhat slower than DCOP due to data validation

and more "layers" in the reference implementation. A comparison

hasn't been posted to the list though.

</p><p>

At this time, KDE has not committed to using D-Bus, but there have

been discussions of KDE bridging D-Bus and DCOP, or even changing

DCOP's implementation to use D-Bus internally (so that GNOME and KDE

would end up using exactly the same bus). See the KDE mailing list

archives for some of these discussions.

</p></td></tr><tr class="question" title="17."><td align="left" valign="top"><p>17.</p></td><td align="left" valign="top"><p>

How does D-Bus differ from [yet more IPC mechanisms]?

</p></td></tr><tr class="answer"><td align="left" valign="top"></td><td align="left" valign="top"><p>

Start by reading Q: 9.

</p><p>

There are countless uses of network sockets in the world. MBUS, Sun ONC/RPC, Jabber/XMPP,

SIP, are some we can think of quickly.

</p></td></tr><tr class="question" title="18."><td align="left" valign="top"><p>18.</p></td><td align="left" valign="top"><p>

Which IPC mechanism should I use?

</p></td></tr><tr class="answer"><td align="left" valign="top"></td><td align="left" valign="top"><p>

Start by reading Q: 9.

</p><p>

If you're writing an Internet or Intranet application, XML-RPC or SOAP

work for many people. These are standard, available for most languages, simple to debug and easy to use.

</p><p>

If you're writing a desktop application for UNIX, then D-Bus is of course our recommendation for talking to other parts of the desktop session.

```

</p><p>
    D-Bus is also designed for communications between system
daemons and
    communications between the desktop and system daemons.
</p><p>
    If you're doing something complicated such as clustering,
    distributed swarms, peer-to-peer, or whatever then
    the authors of this FAQ don't have expertise in these
    areas and you should ask someone else or try a search
engine.
    D-Bus is most likely a poor choice but could be appropriate
    for some things.
</p><p>
    Note: the D-Bus mailing list is probably not the place to
    discuss which system is appropriate for your application,
    though you are welcome to ask specific questions about
    D-Bus <span class="emphasis"><em>after reading this FAQ, the
tutorial, and
        searching the list archives</em></span>. The best way
        to search the list archives is probably to use
        an Internet engine such as Google. On Google,
        include "site:freedesktop.org" in your search.

```

```
<qandaset id="faq">
```

```
<qandaentry>
  <question>
    <para>
      What is D-Bus?
    </para>
  </question>
  <answer>
    <para>
      This is probably best answered by reading the D-Bus <ulink
      url="dbus-tutorial.html">tutorial</ulink> or
      the introduction to the <ulink url="dbus-
      specification.html">specification</ulink>. In
      short, it is a system consisting of 1) a wire protocol for
      exposing a
      typical object-oriented language/framework to other
      applications; and
      2) a bus daemon that allows applications to find and monitor
      one another.
      Phrased differently, D-Bus is 1) an interprocess
      communication (IPC) system and 2) some higher-level
      structure (lifecycle tracking, service activation, security
      policy) provided by two bus daemons,
      one systemwide and one per-user-session.
    </para>
  </answer>
</qandaentry>

<qandaentry>
  <question>
    <para>
```

Is D-Bus stable/finished?

The low-level library "libdbus" and the protocol specification are considered ABI stable. The [README](#) file has a discussion of the API/ABI stability guarantees. Higher-level bindings (such as those for Qt, GLib, Python, Java, C#) each have their own release schedules and degree of maturity, not linked to the low-level library and bus daemon release. Check the project page for the binding you're considering to understand that project's policies.

How is the reference implementation licensed? Can I use it in proprietary applications?

The short answer is yes, you can use it in proprietary applications. You should read the [COPYING](#) file, which offers you the choice of two licenses. These are the GPL and the AFL. The GPL requires that your application be licensed under the GPL as well. The AFL is an "X-style" or "BSD-style" license compatible with proprietary licensing, but it does have some requirements; in particular it prohibits you from filing a lawsuit alleging that the D-Bus software infringes your patents *while you continue to use D-Bus*. If you're going to sue, you have to stop using the software. Read the licenses to determine their meaning, this FAQ

entry is not intended to change the meaning or terms of the licenses.

</para>
</answer>
</qandaentry>

<qandaentry>
<question>

<para>
What is the difference between a bus name, and object path, and an interface?

</para>
</question>

<answer>
<para>

If you imagine a C++ program that implements a network service, then the bus name is the hostname of the computer running this C++ program, the object path is a C++ object instance pointer, and an interface is a C++ class (a pure virtual or abstract class, to be exact).

</para>
<para>

In Java terms, the object path is an object reference, and an interface is a Java interface.

</para>
<para>

People get confused because if they write an application with a single object instance and a single interface, then the bus name, object path, and interface look redundant. For example, you might have a text editor that uses the bus name

<literal>org.freedesktop.TextEditor</literal>, has a global singleton object called <literal>/org/freedesktop/TextEditor</literal>, and that singleton object could implement the interface <literal>org.freedesktop.TextEditor</literal>.

</para>
<para>

However, a text editor application could as easily own multiple bus names (for example, <literal>org.kde.KWrite</literal> in addition to generic <literal>TextEditor</literal>), have multiple objects (maybe <literal>/org/kde/documents/4352</literal> where the number changes according to the document), and each object could implement multiple interfaces, such as

<literal>org.freedesktop.DBus.Introspectable</literal>,

```
        <literal>org.freedesktop.BasicTextField</literal>,
        <literal>org.kde.RichTextDocument</literal>.
    </para>
</answer>
</qandaentry>
```

```
<qandaentry id="service">
  <question>
    <para>
      What is a "service"?
    </para>
  </question>
  <answer>
    <para>
      A service is a program that can be launched by the bus
daemon
      to provide some functionality to other programs. Services
      are normally launched according to the bus name they will
      have.
    </para>
    <para>
      People often misuse the word "service" for any
      bus name, but this tends to be ambiguous and confusing so is
discouraged.
      In the D-Bus docs we try to use "service" only when talking
about
      programs the bus knows how to launch, i.e. a service always
has a
      .service file.
    </para>
  </answer>
</qandaentry>
```

```
<qandaentry id="components">
  <question>
    <para>
      Is D-Bus a "component system"?
    </para>
  </question>
  <answer>
    <para>
      It helps to keep these concepts separate in your mind:
    <orderedlist>
      <listitem>
        <para>
          Object/component system
        </para>
      </listitem>
      <listitem>
        <para>
          GUI control/widget embedding interfaces
        </para>
      </listitem>
    </orderedlist>
  </answer>
</qandaentry>
```

```
        </para>
    </listitem>
    <listitem>
        <para>
            Interprocess communication system or wire protocol
        </para>
    </listitem>
</orderedlist>
</para>
<para>
    D-Bus is not a component system. "Component system" was
originally defined by COM, and was essentially a workaround for the
limitations of the C++ object system (adding introspection, runtime
location of objects, ABI guarantees, and so forth). With the C# language
and CLR, Microsoft added these features to the primary object system,
leaving COM obsolete. Similarly, Java has much less need for
something like COM than C++ did. Even QObject (from Qt) and GObject (from
GLib) offer some of the same features found in COM.
</para>
<para>
    Component systems are not about GUI control embedding.
Embedding a spreadsheet in a word processor document is a matter of
defining some specific <emphasis>interfaces</emphasis> that objects
can implement. These interfaces provide methods related to
GUI controls. So an object implementing those interfaces
can be embedded.
</para>
<para>
    The word "component" just means "object with some fancy
features" and in modern languages all objects are effectively
"components."
</para>
<para>
    So components are fancy objects, and some objects are GUI
controls.
</para>
<para>
    A third, unrelated feature is interprocess communication or
IPC.
    D-Bus is an IPC system. Given an object (or "component" if
you must),
```

you can expose the functionality of that object over an IPC system.

Examples of IPC systems are DCOM, CORBA, SOAP, XML-RPC, and D-Bus.

You can use any of these IPC systems with any object/component system, though some of them are "tuned" for specific object systems. You can think of an IPC system primarily as a wire protocol.

If you combine an IPC system with a set of GUI control interfaces, then you can have an out-of-process or dynamically-loaded GUI control.

Another related concept is the `<firstterm>plugin</firstterm>` or `<firstterm>extension</firstterm>`. Generic plugin systems such as the

`<ulink url="http://eclipse.org">Eclipse</ulink>` system are not so different

from component/object systems, though perhaps a "plugin" tends to be a

bundle of objects with a user-visible name and can be downloaded/packaged as a unit.

`</para>`
`</answer>`
`</qandaentry>`

`<qandaentry id="speed">`

`<question>`

`<para>`

How fast is the D-Bus reference implementation?

`</para>`

`</question>`

`<answer>`

`<para>`

Of course it depends a bit on what you're doing.

`<ulink url="http://lists.freedesktop.org/pipermail/dbus/2004-November/001779.html">`

This mail`</ulink>` contains some benchmarking. At the time of that

benchmark, D-Bus one-to-one communication was about 2.5x slower than

simply pushing the data raw over a socket. After the recent rewrite of

the marshaling code, D-Bus is slower than that because a lot of

optimization work was lost. But it can probably be sped up again.

</para>
<para>
D-Bus communication with the intermediate bus daemon should
be
(and as last profiled, was) about twice as slow as one-to-
one
mode, because a round trip involves four socket reads/writes
rather
than two socket reads/writes.

</para>
<para>
The overhead comes from a couple of places; part of it is
simply
"abstraction penalty" (there are layers of code to support
multiple main loops, multiple transport types, security,
etc.).

Probably the largest part comes from data validation
(because the reference implementation does not trust
incoming data).
It would be simple to add a "no validation" mode, but
probably
not a good idea all things considered.

</para>
<para>
Raw bandwidth isn't the only concern; D-Bus is designed to
enable asynchronous communication and avoid round trips.
This is frequently a more important performance issue
than throughput.
</para>
</answer>
</qandaentry>

<qandaentry id="size">
<question>
<para>
How large is the D-Bus reference implementation?
</para>
</question>
<answer>
<para>
A production build (with assertions, unit tests, and verbose
logging
disabled) is on the order of a 150K shared library.
</para>
<para>
A much, much smaller implementation would be possible by
omitting out
of memory handling, hardcoding a main loop (or always using
blocking
I/O), skipping validation, and otherwise simplifying things.
</para>

</answer>
</qandaentry>

<qandaentry id="other-ipc">

<question>

<para>

How does D-Bus differ from other interprocess communication or networking protocols?

</para>

</question>

<answer>

<para>

Keep in mind, it is not only an IPC system; it also includes lifecycle tracking, service activation, security policy, and

other

higher-level structure and assumptions.

</para>

<para>

The best place to start is to read the D-Bus [tutorial](#), so you have a concrete idea what D-Bus actually is. If you understand other protocols on a wire format level, you may also want to read the D-Bus [specification](#) to see what D-Bus looks like on a low level.

</para>

<para>

As the [tutorial](#) and [specification](#) both explain, D-Bus is tuned

for some specific use cases. Thus, it probably isn't tuned for what you want to do, unless you are doing the things D-Bus was designed for. Don't make the mistake of thinking that any system involving "IPC" is the same thing.

</para>

<para>

The D-Bus authors would not recommend using D-Bus for applications where it doesn't make sense. The following questions compare D-Bus to some other protocols primarily to help you understand D-Bus and decide whether it's appropriate; D-Bus is neither

intended

nor claimed to be the right choice for every application.

</para>

<para>

It should be possible to bridge D-Bus to other IPC systems, just as D-Bus can be bridged to object systems.

</para>

<para>

Note: the D-Bus mailing list subscribers are *very* much not

interested

One True System. So if you want to discuss that, please use another forum.

</para>
</answer>
</qandaentry>

<qandaentry id="corba">

<question>

<para>

How does D-Bus differ from CORBA?

</para>

</question>

<answer>

<para>

Start by reading [other-ipc](#).

</para>

<para>

[CORBA](http://www.omg.org) is designed to support

object-oriented IPC between objects, automatically marshalling

parameters as necessary. CORBA is strongly supported by the

[Open Management Group \(OMG\)](http://www.omg.org), which

produces various standards and supporting documents for CORBA and has

the backing of many large organizations. There are many CORBA ORBs

available, both proprietary ORBs and free / open source software ORBs

(the latter include [ORBit](http://orbit-resource.sourceforge.net/),

[MICO](http://www.mico.org/), and [The ACE Orb \(TAO\)](http://www.theaceorb.com/)).

Many organizations continue to use CORBA ORBs for various kinds of

IPC.

</para>

<para>

Both GNOME and KDE have used CORBA and then moved away from it. KDE

had more success with a system called DCOP, and GNOME layered a system

called Bonobo on top of CORBA. Without custom extensions, CORBA does

not support many of the things one wants to do in a desktop environment with the GNOME/KDE architecture.

</para>
<para>
CORBA on the other hand has a number of features of interest
for
enterprise and web application development, though XML
systems such as
SOAP are the latest fad.
</para>
<para>
Like D-Bus, CORBA uses a fast binary protocol (IIOP). Both
systems
work in terms of objects and methods, and have concepts such
as
"oneway" calls. Only D-Bus has direct support for "signals"
as in
Glib/Qt (or Java listeners, or C# delegates).
</para>
<para>
D-Bus hardcodes and specifies a lot of things that CORBA
leaves open-ended,
because CORBA is more generic and D-Bus has two specific
use-cases in mind.
This makes D-Bus a bit simpler.
</para>
<para>
However, unlike CORBA D-Bus does <emphasis>not</emphasis>
specify the
API for the language bindings. Instead, "native" bindings
adapted
specifically to the conventions of a framework such as
QObject,
GObject, C#, Java, Python, etc. are encouraged. The libdbus
reference
implementation is designed to be a backend for bindings of
this
nature, rather than to be used directly. The rationale is
that an IPC
system API should not "leak" all over a program; it should
come into
play only just before data goes over the wire. As an aside,
OMG is
apparently working on a simpler C++ binding for CORBA.
</para>
<para>
Many CORBA implementations such as ORBit are faster than the
libdbus
reference implementation. One reason is that D-Bus
considers data
from the other end of the connection to be untrusted and
extensively
validates it. But generally speaking other priorities were
placed

ahead of raw speed in the libdbus implementation. A fast D-Bus implementation along the lines of ORBit should be possible, of course.

</para>
<para>
On a more trivial note, D-Bus involves substantially fewer acronyms than CORBA.

</para>
</answer>
</qandaentry>

<qandaentry id="xmlrpcsoap">

<question>

<para>

How does D-Bus differ from XML-RPC and SOAP?

</para>

</question>

<answer>

<para>

Start by reading <xref linkend="other-ipc"/>.

</para>

<para>

In <ulink url="http://www.w3.org/TR/SOAP/">SOAP</ulink> and <ulink url="http://www.xmlrpc.com">XML-RPC</ulink>, RPC calls are transformed into an XML-based format, then sent over the wire (typically using the HTTP protocol), where they are processed and returned. XML-RPC is the simple protocol (its spec is only a page or two), and SOAP is the full-featured protocol.

</para>

<para>

XML-RPC and SOAP impose XML parsing overhead that is normally irrelevant in the context of the Internet, but significant for constant fine-grained IPC among applications in a desktop session.

</para>

<para>

D-Bus offers persistent connections and with the bus daemon supports lifecycle tracking of other applications connected to the bus. With XML-RPC and SOAP, typically each method

call

exists in isolation and has its own HTTP connection.

</para>

</answer>
</qandaentry>

<qandaentry id="dce">

<question>

<para>

How does D-Bus differ from DCE?

</para>

</question>

<answer>

<para>

Start by reading <xref linkend="other-ipc"/>.

</para>

<para>

<ulink url="http://www.opengroup.org/dce/">Distributed
Computing Environment (DCE)</ulink> is an industry-standard vendor-
neutral standard that includes an IPC mechanism. <ulink
url="http://www.opengroup.org/comm/press/05-01-12.htm">The
Open Group has released an implementation as open source
software</ulink>. DCE is quite capable, and includes a vast amount of
functionality such as a distributed time service. As the name implies, DCE is
intended for use in a large, multi-computer distributed application. D-
Bus would not be well-suited for this.

</para>

</answer>

</qandaentry>

<qandaentry id="dcom">

<question>

<para>

How does D-Bus differ from DCOM and COM?

</para>

</question>

<answer>

<para>

Start by reading <xref linkend="other-ipc"/>.

</para>

<para>

Comparing D-Bus to COM is apples and oranges;
see <xref linkend="components"/>.

</para>

<para>

DCOM (distributed COM) is a Windows IPC system designed for
use with

the COM object system. It's similar in some ways to DCE and CORBA.

</para>
</answer>
</qandaentry>

<qandaentry id="internet-communications-engine">

<question>

<para>

How does D-Bus differ from ZeroC's Internet Communications Engine (Ice)

</para>

</question>

<answer>

<para>

Start by reading [other-ipc](#).

</para>

<para>

The [Internet Communications Engine \(Ice\)](http://www.zeroc.com/ice.html) is a powerful IPC

mechanism more

on the level of SOAP or CORBA than D-Bus. Ice has a "dual-
license"

business around it; i.e. you can use it under the GPL, or
pay for a

proprietary license.

</para>

</answer>

</qandaentry>

<qandaentry id="inter-client-exchange">

<question>

<para>

How does D-Bus differ from Inter-Client Exchange (ICE)?

</para>

</question>

<answer>

<para>

[ICE](http://www.x.org/X11R6.8.1/docs/ICE/ice.pdf)

was developed for the X Session Management protocol (XSMP),
as part of

the X Window System (X11R6.1). The idea was to allow desktop
sessions

to contain nongraphical clients in addition to X clients.

</para>

<para>

ICE is a binary protocol designed for desktop use, and KDE's

DCOP

builds on ICE. ICE is substantially simpler than D-Bus (in
contrast

more methods (libICE) to most of the other IPC systems mentioned here, which are complex). ICE doesn't really define a mapping to objects and (DCOP adds that layer). The reference implementation of ICE is often considered to be horrible (and horribly insecure).

DCOP and XSMP are the only two widely-used applications of ICE, and both could in principle be replaced by D-Bus. (Though GNOME and KDE will bother is an open question.)

<qandaentry id="dcop">

<question>

<para>

How does D-Bus differ from DCOP?

</para>

</question>

<answer>

<para>

Start by reading <xref linkend="other-ipc"/>.

</para>

<para>

D-Bus is intentionally pretty similar to <ulink

url="http://developer.kde.org/documentation/library/kdeqt/dcop.html">DCOP</ulink>,

and can be thought of as a "DCOP the next generation" suitable for

sharing between the various open source desktop projects.

</para>

<para>

D-Bus is a bit more complex than DCOP, though the Qt binding for D-Bus

should not be more complex for programmers. The additional complexity

of D-Bus arises from its separation of object references vs. bus names

vs. interfaces as distinct concepts, and its support for one-to-one

connections in addition to connections over the bus. The libdbus

reference implementation has a lot of API to support multiple bindings

and main loops, and performs data validation and out-of-memory handling

in order to support secure applications such as the systemwide bus.

</para>

<para>

D-Bus is probably somewhat slower than DCOP due to data validation

and more "layers" in the reference implementation. A comparison

hasn't been posted to the list though.

</para>

<para>

At this time, KDE has not committed to using D-Bus, but there have

been discussions of KDE bridging D-Bus and DCOP, or even changing

DCOP's implementation to use D-Bus internally (so that GNOME and KDE

would end up using exactly the same bus). See the KDE mailing list

archives for some of these discussions.

</para>

</answer>

</qandaentry>

<qandaentry id="yet-more-ipc">

<question>

<para>

How does D-Bus differ from [yet more IPC mechanisms]?

</para>

</question>

<answer>

<para>

Start by reading <xref linkend="other-ipc"/>.

</para>

<para>

There are countless uses of network sockets in the world.

<ulink

url="http://www.mbus.org/">MBUS</ulink>, Sun ONC/RPC, Jabber/XMPP,

SIP, are some we can think of quickly.

</para>

</answer>

</qandaentry>

<question>

<para>

Which IPC mechanism should I use?

```
</para>
</question>
<answer>
  <para>
    Start by reading <xref linkend="other-ipc"/>.
  </para>
  <para>
    If you're writing an Internet or Intranet application, XML-
RPC or SOAP
    work for many people. These are standard, available for most
    languages, simple to debug and easy to use.
  </para>
  <para>
    If you're writing a desktop application for UNIX,
    then D-Bus is of course our recommendation for
    talking to other parts of the desktop session.
  </para>
  <para>
    D-Bus is also designed for communications between system
daemons and
    communications between the desktop and system daemons.
  </para>
  <para>
    If you're doing something complicated such as clustering,
    distributed swarms, peer-to-peer, or whatever then
    the authors of this FAQ don't have expertise in these
    areas and you should ask someone else or try a search
engine.
    D-Bus is most likely a poor choice but could be appropriate
    for some things.
  </para>
  <para>
    Note: the D-Bus mailing list is probably not the place to
    discuss which system is appropriate for your application,
    though you are welcome to ask specific questions about
    D-Bus <emphasis>after reading this FAQ, the tutorial, and
    searching the list archives</emphasis>. The best way
    to search the list archives is probably to use
    an Internet engine such as Google. On Google,
    include "site:freedesktop.org" in your search.
  </para>

```

```
<em  
class="parameter"><code><span class="type">DBusError</span>  
*derror</code></em>);</pre>
```

Store the information from a Dbus method error return into a GError. For the normal case of an arbitrary remote process, the error code will be DBUS_GERROR_REMOTE_EXCEPTION. Now, Dbus errors have two components; a message and a "name". The former is an arbitrary (normally American English) string. The second is a string like com.example.FooFailure which programs can use as a conditional source. Because a GError only has one string, we use a hack to encode both values:

```
</p>  
&lt;human readable string&gt;&lt;null&gt;&lt;error  
name&gt;&lt;null&gt;
```

You can use the following code to retrieve both values:

```
</p>  
<div class="informalexample">

<hr>
<div class="refsect2">
<a name="dbus-g-object-type-register-shadow-
property"></a><h3>dbus_g_object_type_register_shadow_property ()</h3>
<pre class="programlisting"><span class="returnvalue">void</span>
dbus_g_object_type_register_shadow_property
(
<em
class="parameter"><code><a
href="http://library.gnome.org/devel/gobject/unstable/gobject-Type-
Information.html#GType"><span class="type">GType</span></a>
iface_type</code></em>,

```

```
class="parameter"><code>const <span class="type">char</span>
*dbus_prop_name</code></em>,</pre>
```

```
class="parameter"><code>const <span class="type">char</span>
*shadow_prop_name</code></em>);</pre>
```

<p>

Registers a new property name <em

class="parameter"><code>shadow_prop_name</code> that overrides
the

<em class="parameter"><code>dbus_prop_name</code> in D-Bus

property get/set requests. Since all properties for

all interfaces implemented by a GObject exist in the same namespace,
this

allows implementations to use the same property name in two or more D-
Bus

interfaces implemented by the same GObject, as long as one of those D-
Bus

interface properties is registered with a shadow property name.

</p>

<p>

For example, if both org.foobar.Baz.InterfaceA and

org.foobar.Baz.InterfaceB

have a D-Bus property called "Bork", the developer assigns a shadow
property

name to the conflicting property name in one or both of these
GInterfaces to

resolve the conflict. Assume the GInterface implementing

org.foobar.Baz.InterfaceA registers a shadow property called "a-bork",
while

the GInterface implementing org.foobar.Baz.InterfaceB registers a
shadow

property called "b-bork". The GObject implementing both these
GInterfaces

would then use #<a

href="http://library.gnome.org/devel/gobject/unstable/gobject-The-
Base-Object-Type.html#g-object-class-override-property"><code

class="function">g_object_class_override_property()</code> to
implement both

"a-bork" and "b-bork" and D-Bus requests for "Bork" on either D-Bus
interface

will not conflict.

</p>

[Description](#)

A [DBusGMessage](#) is a boxed type abstracting a `DBusMessage`.

[Details](#)

```
typedef struct _DBusGMessage
DBusGMessage;
```

A [DBusGMessage](#) is a boxed type abstracting a `DBusMessage` from `libdbus`.

[DBUS_TYPE_G_MESSAGE](#)

```
#define DBUS_TYPE_G_MESSAGE
(dbus_g_message_get_g_type ())
```

Expands to a function call returning the boxed [GType](#) of a [DBusGConnection](#).

<p><code>dbus_g_message_get_g_type</code> : the <code>GLib</code> type</p>
--

```
dbus_g_message_ref ()
DBusGMessage * dbus_g_message_ref
(DBusGMessage DBusGMessage *message);
```

```

<p>
Increment refcount on a <a class="link" href="dbus-glib-
DBusGMessage.html#DBusGMessage" title="DBusGMessage"><span

```

<p>

Creates a new proxy for a remote interface exported by a connection on a message bus. Method calls and signal connections over this proxy will go to the name owner; the name's owner is expected to support the given interface name. THE NAME OWNER MAY CHANGE OVER TIME, for example between two different method calls, unless the name is a unique name. If you need a fixed owner, you need to request the current owner and bind a proxy to its unique name rather than to the generic name; see

<code class="function">dbus_g_proxy_new_for_name_owner()</code>.

</p>

<p>

A name-associated proxy only makes sense with a message bus, not for app-to-app direct dbus connections.

</p>

<p>

This proxy will only emit the "destroy" signal if the DBusConnection is disconnected, the proxy has no remaining references, or the name is a unique name and its owner disappears. If a well-known name changes owner, the proxy will still be alive.

</p>

<div class="variablelist"><table border="0">

<col align="left" valign="top">

<tbody>

<tr>

<td><p><em class="parameter"><code>connection</code>Â :</p></td>

<td>the connection to the remote bus</td>

</tr>

<tr>

<td><p><em class="parameter"><code>name</code>Â :</p></td>

<td>any name on the message bus</td>

<em class="parameter"><code><a href="http://library.gnome.org/devel/glib/unstable/glib-Error-Reporting.html#GError"><span class="type">GError</span></a>
**error</code></em>);</pre>

Similar to dbus\_g\_proxy\_new\_for\_name \(\), but makes a round-trip request to the message bus to get the current name owner, then binds the proxy to the unique name of the current owner, rather than to the well-known name. As a result, the name owner will not change over time, and the proxy will emit the "destroy" signal when the owner disappears from the message bus.

```

</p>

<p>

An example of the difference between [dbus-g-proxy-new-for-name](dbus-glib-DBusGProxy.html#dbus-g-proxy-new-for-name)

`dbus_g_proxy_new_for_name ()`

`dbus_g_proxy_new_for_name ()`

and [dbus-g-proxy-new-for-name-owner](dbus-glib-DBusGProxy.html#dbus-g-proxy-new-for-name-owner)

`dbus_g_proxy_new_for_name_owner ()`

`dbus_g_proxy_new_for_name_owner ()`: if you

provide the well-known name

`"org.freedesktop.Database"` [dbus-g-proxy-new-for-name](dbus-glib-DBusGProxy.html#dbus-g-proxy-new-for-name)

`dbus_g_proxy_new_for_name ()`

`dbus_g_proxy_new_for_name ()` remains bound

to that name as it changes owner. [dbus-g-proxy-new-for-name-owner](dbus-glib-DBusGProxy.html#dbus-g-proxy-new-for-name-owner)

`dbus_g_proxy_new_for_name_owner ()`

`dbus_g_proxy_new_for_name_owner ()`

will fail if the name has no owner. If the name has an owner,

[dbus-g-proxy-new-for-name-owner](dbus-glib-DBusGProxy.html#dbus-g-proxy-new-for-name-owner)

`dbus_g_proxy_new_for_name_owner ()`

`dbus_g_proxy_new_for_name_owner ()` will

bind to the unique name

of that owner rather than the generic name.

</p>

<pre class="programlisting"><span class="returnvalue">void</span>
dbus_g_proxy_send
(

```

Sends a message to the interface we're proxying for. Does not block or wait for a reply. The message is only actually written out when you return to the main loop or block in

[`dbus_g_connection_flush\(\)`](dbus-glib-DBusGConnection.html#dbus-g-connection-flush "dbus_g_connection_flush ()")

The message is modified to be addressed to the target interface. That is, a destination name field or whatever is needed will be added to the message. The basic point of this function is to add the necessary header fields, otherwise it's equivalent to `dbus_connection_send()`.

This function adds a reference to the message, so the caller still owns its original reference.

It is an error to call this method on a proxy that has emitted the `destroy` signal.

href="https://www.gnu.org/software/gnutls/reference/gnutls-
crypto.html#int"><span class="type">int</span></a>
timeout</code></em>);</pre>
<p>
Sets the default timeout to use for a proxy. This timeout will be
used in calls where the timeout is not specified, or is specified to
be -1.
If this timeout is also set to -1, libdbus will use a reasonable
default
value.
</p>
<p>
This is useful for long-running operations that takes longer than
the default timeout (which is a on the order of magnitude of tens
of seconds). For some applications, consider using a pattern where
the method returns once the operation is underway
(e.g. immediately) and emits a signal when the operation terminates
(though beware of leaking information with/in the signal return
value).
</p>

    <title>D-Bus GLib bindings - Reference Manual</title>
    <releaseinfo>for version &version;</releaseinfo>
  </bookinfo>

  <chapter>
    <title>Introduction</title>

    <para>D-Bus is a message bus system, a simple way for applications
to talk to one another.</para>

    <para>D-Bus supplies both a system daemon (for events such as "new
hardware device added" or "printer queue changed") and a
per-user-login-session daemon (for general IPC needs among user
applications). Also, the message bus is built on top of a general
one-to-one message passing framework, which can be used by any two
apps to communicate directly (without going through the message
bus daemon). Currently the communicating applications are on one
computer, but TCP/IP option is available and remote support
planned.</para>

```

<para>The D-Bus API isn't finished yet, and the design is by no means set in stone. One of our main goals is for lots of projects to use it, so if you wouldn't use it, by all means mail us and say why - design, licensing, indentation style, we would rather know than not know.</para>

<para>D-Bus' only <emphasis>required</emphasis> dependency is an XML parser (either libxml or expat). D-Bus includes many language bindings to the D-Bus system, if you want to build those. The list of projects using D-Bus is growing and they provide a wealth of examples of using the various APIs to learn from.</para>

<para>Trying out D-Bus in sample applications is encouraged - we want to get it widely used and tested. It should be working pretty well these days, and when it isn't bug reports are very welcome.</para>

<para>For more information on D-Bus, see
<ulink url="http://www.freedesktop.org/wiki/Software/dbus">
http://www.freedesktop.org/wiki/Software/dbus</ulink>.&br/></para>

</chapter>

<a name="dbus-glib-Specializable-GType-
System.description"></a><h2>Description</h2>
<p>
Specialized gtypes are basically a way to allow the definition of
recursive <a
href="http://library.gnome.org/devel/gobject/unstable/gobject-Type-
Information.html#GType"><span class="type">GTypes</span></a>. It
allows the definition of 'containers' which is
basically a user defined structure capable of holding other data, and
a
set of functions defining how to access that structure. Containers
come in
3 flavors: collections, maps and structs.
</p>
<p>
A collection is a container that holds an ordered set of items, all
of which must be the same type. (This is an <span
class="emphasis"><em>array</em></span>
in standard D-Bus terminology.) dbus-glib specialized collections can
be
<a href="http://library.gnome.org/devel/glib/unstable/glib-
Arrays.html#GArray"><span class="type">GArray</span></a> (for numeric
elements), <a href="http://library.gnome.org/devel/glib/unstable/glib-
Pointer-Arrays.html#GPtrArray"><span class="type">GPtrArray</span></a>
(for string, object or
boxed elements), <a
href="http://library.gnome.org/devel/glib/unstable/glib-Singly-Linked-
Lists.html#GSList"><span class="type">GSList</span></a> (for boxed
elements, not recommended), or a
user-defined type.
</p>
<p>
A map is a container that holds a set of key/value pairs.

```

The keys have one type, and the values another; the type of the keys must be a numeric or string-like type. (This is a dict (dictionary) or array of dict entry in standard D-Bus terminology.) dbus-glib specialized maps can be [GHashTable or a user-defined type.](http://library.gnome.org/devel/glib/unstable/glib-Hash-Tables.html#GHashTable)

</p>

<p>

A struct is a container that holds a fixed number of members, each member

having a predefined type. (This is a struct in standard D-Bus terminology.) It is analogous to the C <code>struct</code> keyword, but dbus-glib does not generally represent D-Bus structs in C structs. dbus-glib specialized structs can be [GValueArray or a user-defined type.](http://library.gnome.org/devel/gobject/unstable/gobject-Value-arrays.html#GValueArray)

</p>

<p>

A specialization is a GType detailing a particular container with particular types (a type specialization).

</p>

<p>

Functions are provided for constructing and manipulating specializations.

</p>

<p>

This documentation needs splitting into two pages, one for defining new containers and using existing containers. I expect most users to only do the latter. I also need to add some examples.

</p>

The value must either be a simple value (integer, string, boolean, object path etc.) or a specialized container registered with

`dbus_g_type_get_collection ()`

`dbus_g_type_get_collection()`, [dbus_g_type_get_map \(\)](dbus-glib-Specializable-GType-System.html#dbus-g-type-get-map "dbus_g_type_get_map ()") or [dbus_g_type_get_struct \(\)](dbus-glib-Specializable-GType-System.html#dbus-g-type-get-struct "dbus_g_type_get_struct ()"). Providing any other type is a programming error (including as a child type).

/**
 * dbus_g_object_type_register_shadow_property:
 * @iface_type: #GType for the #GInterface
 * @dbus_prop_name: D-Bus property name (as specified in the
introspection data)
 * to override with the shadow property name (as specified in the
GType's
 * initialization function, ie glib-style)
 * @shadow_prop_name: property name which should override the shadow
property
 *
 * Registers a new property name @shadow_prop_name that overrides the
 * @dbus_prop_name in D-Bus property get/set requests. Since all
properties for
 * all interfaces implemented by a GObject exist in the same
namespace, this
 * allows implementations to use the same property name in two or more
D-Bus
 * interfaces implemented by the same GObject, as long as one of those
D-Bus
 * interface properties is registered with a shadow property name.
 *
 * For example, if both org.foobar.Baz.InterfaceA and
org.foobar.Baz.InterfaceB
 * have a D-Bus property called "Bork", the developer assigns a shadow
property
 * name to the conflicting property name in one or both of these
GInterfaces to
 * resolve the conflict. Assume the GInterface implementing
 * org.foobar.Baz.InterfaceA registers a shadow property called "a-
bork", while
 * the GInterface implementing org.foobar.Baz.InterfaceB registers a
shadow
 * property called "b-bork". The GObject implementing both these
GInterfaces
 * would then use #g_object_class_override_property() to implement
both
 * "a-bork" and "b-bork" and D-Bus requests for "Bork" on either D-Bus
interface
 * will not conflict.
