/**
 * dbus_set_g_error:
 * @gerror: an error
 * @derror: a #DBusError
 *
 * Store the information from a Dbus method error return into a
 * GError. For the normal case of an arbitrary remote process,
 * the error code will be DBUS_GERROR_REMOTE_EXCEPTION. Now,
 * Dbus errors have two components; a message and a "name".
 * The former is an arbitrary (normally American English) string.
 * The second is a string like com.example.FooFailure which
 * programs can use as a conditional source. Because a GError
 * only has one string, we use a hack to encode both values:
 *
 * <human readable string>&null&error
name&null&
 *
 * You can use the following code to retrieve both values:
 *
 * |[const char *msg = error->message;
 * size_t len = strlen(msg);
 * const char *error_name = msg+len+1;]|

#include <string.h>
#include <gobject/gvaluecollector.h>

/**
 * SECTION:dbus-gtype-specialized
 * @short_description: Specialized GTypes
 * @stability: Unstable
 *
 * Specialized gtypes are basically a way to allow the definition of
 * recursive #GTypes. It allows the definition of 'containers' which
 is
 * basically a user defined structure capable of holding other data,
 and a
 * set of functions defining how to access that structure. Containers
 come in
 * 3 flavors: collections, maps and structs.
 *
 * A collection is a container that holds an ordered set of items, all
 * of which must be the same type. (This is an
<emphasis>array</emphasis>
 * in standard D-Bus terminology.) dbus-glib specialized collections
 can be
 * #GArray (for numeric elements), #GPtrArray (for string, object or
 * boxed elements), #GSLList (for boxed elements, not recommended), or
 a
 * user-defined type.
 *
 * A map is a container that holds a set of key/value pairs.
 * The keys have one type, and the values another; the type of the
 keys
 * must be a numeric or string-like type. (This is a
<emphasis>dict</emphasis>
 * (dictionary) or <emphasis>array of dict entry</emphasis> in
 standard D-Bus
 * terminology.) dbus-glib specialized maps can be #GHashTable or a
 * user-defined type.
 *
 * A struct is a container that holds a fixed number of members, each
 member
 * having a predefined type. (This is a <emphasis>struct</emphasis> in

```

```

* standard D-Bus terminology.) It is analogous to the C @struct
keyword, but
* dbus-glib does not generally represent D-Bus structs in C structs.
* dbus-glib specialized structs can be #GValueArray or a user-defined
type.
*
* A specialization is a GType detailing a particular container with
* particular types (a type specialization).
*
* Functions are provided for constructing and manipulating
specializations.
*
* This documentation needs splitting into two pages, one for defining
new
* containers and using existing containers. I expect most users to
only do
* the latter. I also need to add some examples.
*/

 * Takes a preliminary integer hash value and produces an index into a
 * hash tables bucket list.  The idea is to make it so that
 * preliminary values that are arbitrarily similar will end up in
 * different buckets.  The hash function was taken from a
 * random-number generator.  (This is used to hash integers.)
 *
 * The down_shift drops off the high bits of the hash index, and
 * decreases as we increase the number of hash buckets (to keep more
 * range in the hash index).  The mask also strips high bits and strips
 * fewer high bits as the number of hash buckets increases.
 * I don't understand two things: why is the initial downshift 28
 * to keep 4 bits when the initial mask is 011 to keep 2 bits,

```

```

* and why do we have both a mask and a downshift?

 * @defgroup DBusKeyring keyring class
 * @ingroup DBusInternals
 * @brief DBusKeyring data structure
 *
 * Types and functions related to DBusKeyring. DBusKeyring is intended
 * to manage cookies used to authenticate clients to servers. This is
 * essentially the "verify that client can read the user's homedir"
 * authentication mechanism. Both client and server must have access
 * to the homedir.
 *
 * The secret keys are not kept in locked memory, and are written to a
 * file in the user's homedir. However they are transient (only used
 * by a single server instance for a fixed period of time, then
 * discarded). Also, the keys are not sent over the wire.
 *
 * @todo there's a memory leak on some codepath in here, I saw it once
 * when running make check - probably some specific initial cookies
 * present in the cookie file, then depending on what we do with them.
 */

/* TODO (tl): This Windows version of dbus-launch is currety rather
 * pointless as it doesn't take the same command-line options as the
 * UNIX dbus-launch does. A main point of the dbus-launch command is
 * to pass it for instance a --config-file option to make the started
 * dbus-daemon use that config file.
 *
 * This version also doesn't print out any information, which is a
 * main point of the UNIX one. It should at least support the
 * --sh-syntax option, and maybe also a --cmd-syntax to print out the
 * variable settings in cmd.exe syntax?
 *
 * NOTE (rh): The main task of dbus-launch is (from the man page) to
start
 * a session bus and this is achieved by the current implementation.
 *
 * Additional on windows the session bus starting in not integrated
 * into the logon process, so there is no need for any --syntax
option.
 * In fact (at least for kde on windows) the session bus is
autostarted
 * with the first application requesting a session bus.
 *

.SH NAME
dbus\--launch \-- Utility to start a message bus from a shell script
.SH SYNOPSIS
.SH PP
.B dbus\--launch [\--version] [\--sh\--syntax] [\--csh\--syntax] [\--\--
auto\--syntax] [\--\--exit\--with\--session] [\--\--autolaunch=MACHINEID] [\--
\--config\--file=FILENAME] [PROGRAM] [ARGS...]

```

.SH DESCRIPTION

The `\fIdbus\--launch\fp` command is used to start a session bus instance of `\fIdbus\--daemon\fp` from a shell script. It would normally be called from a user's login scripts. Unlike the daemon itself, `\fIdbus\--launch\fp` exits, so backticks or the `$()` construct can be used to read information from `\fIdbus\--launch\fp`.

With no arguments, `\fIdbus\-\launch\fp` will launch a session bus instance and print the address and PID of that instance to standard output.

You may specify a program to be run; in this case, `\fIdbus\-\launch\fp` will launch a session bus instance, set the appropriate environment variables so the specified program can find the bus, and then execute the specified program, with the specified arguments. See below for examples.

If you launch a program, `\fIdbus\-\launch\fp` will not print the information about the new bus to standard output.

When `\fIdbus\-\launch\fp` prints bus information to standard output, by default it is in a simple key-value pairs format. However, you may request several alternate syntaxes using the `\-\-sh\-\syntax`, `\-\-csh\-\syntax`, `\-\-binary\-\syntax`, or `\-\-auto\-\syntax` options. Several of these cause `\fIdbus\-\launch\fp` to emit shell code to set up the environment.

With the `\-\-auto\-\syntax` option, `\fIdbus\-\launch\fp` looks at the value of the SHELL environment variable to determine which shell syntax should be used. If SHELL ends in "csh", then csh-compatible code is emitted; otherwise Bourne shell code is emitted. Instead of passing `\-\-auto\-\syntax`, you may explicitly specify a particular one by using `\-\-sh\-\syntax` for Bourne syntax, or `\-\-csh\-\syntax` for csh syntax. In scripts, it's more robust to avoid `\-\-auto\-\syntax` and you hopefully know which shell your script is written in.

.PP

See <http://www.freedesktop.org/software/dbus/> for more information about D-Bus. See also the man page for `\fIdbus\-\daemon\fp`.

.SH EXAMPLES

Distributions running

`.B dbus\-\launch`

as part of a standard X session should run

`.B "dbus\-\launch \-\-exit\-\with\-\session"`

after the X server has started and become available, as a wrapper around

the "main" X client (typically a session manager or window manager), as in

these examples:

.RS

```
.B "dbus\--launch \--exit\--with\--session gnome\--session"
.B "dbus\--launch \--exit\--with\--session openbox"
.B "dbus\--launch \--exit\--with\--session ~/.xsession"
.RE
```

If your distribution does not do this, you can achieve similar results by running your session or window manager in the same way in a script run by your X session, such as

```
.BR ~/.xsession ,
.B ~/.xinitrc
or
.BR ~/.Xclients .
```

To start a D-Bus session within a text-mode session, you can run `dbus-launch` in the background. For instance, in a `sh-compatible` shell:

```
.nf
  ## test for an existing bus daemon, just to be safe
  if test \-z "$DBUS_SESSION_BUS_ADDRESS" ; then
    ## if not found, launch a new one
    eval `dbus\--launch \--sh\--syntax`
    echo "D\--Bus per\--session daemon address is:
$DBUS_SESSION_BUS_ADDRESS"
  fi
.fi
```

Note that in this case, `dbus-launch` will exit, and `dbus-daemon` will not be terminated automatically on logout.

.SH AUTOMATIC LAUNCHING

.PP

If `DBUS_SESSION_BUS_ADDRESS` is not set for a process that tries to use `D\--Bus`, by default the process will attempt to invoke `dbus\--launch` with the `\--autolaunch` option to start up a new session bus or find the existing bus address on the X display or in a file in `~/.dbus/session\--bus/`

.PP

Whenever an autolaunch occurs, the application that had to start a new bus will be in its own little world; it can effectively end up starting a whole new session if it tries to use a lot of bus services. This can be suboptimal or even totally broken, depending on the app and what it tries to do.

.PP

There are two common reasons for autolaunch. One is `ssh` to a remote machine. The ideal fix for that would be forwarding of `DBUS_SESSION_BUS_ADDRESS` in the same way that `DISPLAY` is forwarded.

In the meantime, you can edit the session.conf config file to have your session bus listen on TCP, and manually set DBUS_SESSION_BUS_ADDRESS, if you like.

.PP

The second common reason for autolaunch is an su to another user, and display of X applications running as the second user on the display belonging to the first user. Perhaps the ideal fix in this case would be to allow the second user to connect to the session bus of the first user, just as they can connect to the first user's display. However, a mechanism for that has not been coded.

.PP

You can always avoid autolaunch by manually setting DBUS_SESSION_BUS_ADDRESS. Autolaunch happens because the default address if none is set is "autolaunch:", so if any other address is set there will be no autolaunch. You can however include autolaunch in an explicit session bus address as a fallback, for example DBUS_SESSION_BUS_ADDRESS="something:,autolaunch:" \- in that case if the first address doesn't work, processes will autolaunch. (The bus address variable contains a comma\-separated list of addresses to try.)

.PP

The \-\-autolaunch option is considered an internal implementation detail of libdbus, and in fact there are plans to change it. There's no real reason to use it outside of the libdbus implementation anyhow.

.SH OPTIONS

The following options are supported:

.TP

.I "\-\-auto\-\-syntax"

Choose \-\-csh\-\-syntax or \-\-sh\-\-syntax based on the SHELL environment variable.

.I "\-\-binary\-\-syntax"

Write to stdout a nul\-terminated bus address, then the bus PID as a binary integer of size sizeof(pid_t), then the bus X window ID as a binary integer of size sizeof(long). Integers are in the machine's byte order, not network byte order or any other canonical byte order.

.TP

.I "\-\-close\-\-stderr"

Close the standard error output stream before starting the D\-\-Bus daemon. This is useful if you want to capture dbus\-\-launch error messages but you don't want dbus\-\-daemon to keep the stream open to your application.

.TP

.I "\-\-config\-\-file=FILENAME"

Pass \-\-config\-\-file=FILENAME to the bus daemon, instead of passing it

the `--session` argument. See the man page for `dbus-daemon`

.TP

.I "--csh-syntax"

Emit `cs` compatible code to set up environment variables.

.TP

.I "--exit-with-session"

If this option is provided, a persistent "babysitter" process will be created that watches `stdin` for HUP and tries to connect to the X server. If this process gets a HUP on `stdin` or loses its X connection, it kills the message bus daemon.

.TP

.I "--autolaunch=MACHINEID"

This option implies that `dbus-launch` should scan for a previously-started session and reuse the values found there. If no session is found, it will start a new session. The `--exit-with-session` option is implied if `--autolaunch` is given. This option is for the exclusive use of `libdbus`, you do not want to use it manually. It may change in the future.

.TP

.I "--sh-syntax"

Emit Bourne-shell compatible code to set up environment variables.

.TP

.I "--version"

Print the version of `dbus-launch`

.SH NOTES

If you run

.B "dbus-launch myapp"

(with any other options), `dbus-daemon` will

.I not

exit when

.B myapp

terminates: this is because

.B myapp

is assumed to be part of a larger session, rather than a session in its

own right.

/* PROCESSES
```

```

*
* If you are in a shell and run "dbus-launch myapp", here is what
happens:
*
* shell [*]
*   \- main()                --exec--> myapp[*]
*     \- "intermediate parent"
*       \- bus-runner        --exec--> dbus-daemon --fork
*         \- babysitter[*]   \- final dbus-daemon[*]
*
* Processes marked [*] survive the initial flurry of activity.
*
* If you run "dbus-launch --sh-syntax" then the diagram is the same,
except
* that main() prints variables and exits 0 instead of exec'ing myapp.
*
* PIPES
*
* dbus-daemon --print-pid      -> bus_pid_to_launcher_pipe      -> main
* dbus-daemon --print-address -> bus_address_to_launcher_pipe -> main
* main                        -> bus_pid_to_babysitter_pipe  ->
babysitter
*
* The intermediate parent looks pretty useless at first glance. Its
purpose
* is to avoid the bus-runner becoming a zombie: when the intermediate
parent
* terminates, the bus-runner and babysitter are reparented to init,
which
* reaps them if they have finished. We can't rely on main() to reap
arbitrary
* children because it might exec myapp, after which it can't be
relied on to
* reap its children. We can rely on main() to reap the intermediate
parent,
* because that happens before it execs myapp.
*
* It's unclear why dbus-daemon needs to fork, but we explicitly tell
it to
* for some reason, then wait for it. If we left it undefined, a
forking
* dbus-daemon would get the parent process reparented to init and
reaped
* when the intermediate parent terminated, and a non-forking dbus-
daemon
* would get reparented to init and carry on there.
*
* myapp is exec'd by the process that initially ran main() so that
it's
* the shell's child, so the shell knows how to do job control and
stuff.

```

```
 * This is desirable for the "dbus-launch an application" use-case,  
less so  
 * for the "dbus-launch a test suite in an isolated session" use-case.

<refsect1 id='description'><title>DESCRIPTION</title>

```

<para>The <command>dbus-launch</command> command is used to start a session bus instance of <emphasis remap='I'>dbus-daemon</emphasis> from a shell script.

It would normally be called from a user's login scripts. Unlike the daemon itself, <command>dbus-launch</command> exits, so backticks or the \$() construct can be used to read information from <command>dbus-launch</command>.</para>

<para>With no arguments, <command>dbus-launch</command> will launch a session bus instance and print the address and pid of that instance to standard output.</para>

<para>You may specify a program to be run; in this case, <command>dbus-launch</command> will launch a session bus instance, set the appropriate environment variables so the specified program can find the bus, and then execute the specified program, with the specified arguments. See below for examples.</para>

<para>If you launch a program, <command>dbus-launch</command> will not print the information about the new bus to standard output.</para>

<para>When <command>dbus-launch</command> prints bus information to standard output, by default it is in a simple key-value pairs format. However, you may request several alternate syntaxes using the --sh-syntax, --csh-syntax, --binary-syntax, or --auto-syntax options. Several of these cause <command>dbus-launch</command> to emit shell code to set up the environment.</para>

<para>With the --auto-syntax option, <command>dbus-launch</command> looks at the value of the SHELL environment variable to determine which shell syntax should be used. If SHELL ends in "csh", then csh-compatible code is emitted; otherwise Bourne shell code is emitted. Instead of passing --auto-syntax, you may explicitly specify a particular one by using --sh-syntax for Bourne syntax, or --csh-syntax for csh syntax. In scripts, it's more robust to avoid --auto-syntax and you hopefully know which shell your script is written in.</para>

<para>See <ulink url='http://www.freedesktop.org/software/dbus/'>http://www.freedesktop.org/software/dbus/</ulink> for more information

about D-Bus. See also the man page for `dbus-daemon`.

Here is an example of how to use `dbus-launch` with an sh-compatible shell to start the per-session bus daemon:

```
## test for an existing bus daemon, just to be safe
if test -z "$DBUS_SESSION_BUS_ADDRESS" ; then
    ## if not found, launch a new one
    eval `dbus-launch --sh-syntax --exit-with-session`
    echo "D-Bus per-session daemon address is:
$DBUS_SESSION_BUS_ADDRESS"
fi
```

`<!-- .fi -->`

You might run something like that in your login scripts.

Another way to use `dbus-launch` is to run your main session program, like so:

```
dbus-launch gnome-session
```

`<!-- .fi -->`

The above would likely be appropriate for `~/.xsession` or `~/.Xclients`.

`</refsect1>`

`<refsect1 id='automatic_launching'><title>AUTOMATIC LAUNCHING</title>`

`<para>If DBUS_SESSION_BUS_ADDRESS is not set for a process that tries to use`

`D-Bus, by default the process will attempt to invoke dbus-launch with the --autolaunch option to start up a new session bus or find the existing bus address on the X display or in a file in ~/.dbus/session-bus/`

Whenever an autolaunch occurs, the application that had to start a new bus will be in its own little world; it can effectively end up starting a whole new session if it tries to use a lot of bus services. This can be suboptimal or even totally broken, depending on the app and what it tries to do.

There are two common reasons for autolaunch. One is ssh to a remote

machine. The ideal fix for that would be forwarding of DBUS_SESSION_BUS_ADDRESS in the same way that DISPLAY is forwarded. In the meantime, you can edit the session.conf config file to have your session bus listen on TCP, and manually set DBUS_SESSION_BUS_ADDRESS, if you like.</para>

<para>The second common reason for autolaunch is an su to another user, and display of X applications running as the second user on the display belonging to the first user. Perhaps the ideal fix in this case would be to allow the second user to connect to the session bus of the first user, just as they can connect to the first user's display. However, a mechanism for that has not been coded.</para>

<para>You can always avoid autolaunch by manually setting DBUS_SESSION_BUS_ADDRESS. Autolaunch happens because the default address if none is set is "autolaunch:", so if any other address is set there will be no autolaunch. You can however include autolaunch in an explicit session bus address as a fallback, for example DBUS_SESSION_BUS_ADDRESS="something:,autolaunch:" - in that case if the first address doesn't work, processes will autolaunch. (The bus address variable contains a comma-separated list of addresses to try.)</para>

<para>The --autolaunch option is considered an internal implementation detail of libdbus, and in fact there are plans to change it. There's no real reason to use it outside of the libdbus implementation anyhow.</para>

</refsect1>

<refsect1 id='options'><title>OPTIONS</title>

<para>The following options are supported:</para>

<variablelist remap='TP'>

<varlistentry>

<term><option>--auto-syntax</option></term>

<listitem>

<para>Choose --csh-syntax or --sh-syntax based on the SHELL environment variable.</para>

<para><option>--binary-syntax</option>

Write to stdout a nul-terminated bus address, then the bus PID as a binary integer of size sizeof(pid_t), then the bus X window ID as a binary integer of size sizeof(long). Integers are in the machine's byte order, not network byte order or any other canonical byte order.</para>

</listitem>

</varlistentry>

```
<varlistentry>
<term><option>--close-stderr</option></term>
<listitem>
```

<para>Close the standard error output stream before starting the D-Bus daemon. This is useful if you want to capture dbus-launch error messages but you don't want dbus-daemon to keep the stream open to your application.</para>

```
</listitem>
</varlistentry>
<varlistentry>
<term><option>--config-file=FILENAME</option></term>
<listitem>
```

<para>Pass --config-file=FILENAME to the bus daemon, instead of passing it the --session argument. See the man page for dbus-daemon</para>

```
</listitem>
</varlistentry>
<varlistentry>
<term><option>--csh-syntax</option></term>

/* In the variable-length case, we have to fix alignment after we
insert.
* The strategy is as follows:
*
* - pad a new string to have the same alignment as the
*   start of the current basic value
* - write the new basic value
* - copy from the original reader to the new string,
*   which will fix the alignment of types following
*   the new value
* - this copy has to start at realign_root,
*   but not really write anything until it
*   passes the value being set
* - as an optimization, we can stop copying
*   when the source and dest values are both
*   on an 8-boundary, since we know all following
*   padding and alignment will be identical
* - copy the new string back to the original
*   string, replacing the relevant part of the
*   original string
* - now any arrays in the original string that
*   contained the replaced string may have the

```

```

*      wrong length; so we have to fix that

/**
 * Sets a new value for the basic type value pointed to by the reader,
 * leaving the reader valid to continue reading. Any other readers
 * will be invalidated if you set a variable-length type such as a
 * string.
 *
 * The provided realign_root is the reader to start from when
 * realigning the data that follows the newly-set value. The reader
 * parameter must point to a value below the realign_root parameter.
 * If the type being set is fixed-length, then realign_root may be
 * #NULL. Only values reachable from realign_root will be realigned,
 * so if your string contains other values you will need to deal with
 * those somehow yourself. It is OK if realign_root is the same
 * reader as the reader parameter, though if you aren't setting the
 * root it may not be such a good idea.
 *
 * @todo DBusTypeReader currently takes "const" versions of the type
 * and value strings, and this function modifies those strings by
 * casting away the const, which is of course bad if we want to get
 * picky. (To be truly clean you'd have an object which contained the
 * type and value strings and set_basic would be a method on that
 * object... this would also make DBusTypeReader the same thing as
 * DBusTypeMark. But since DBusMessage is effectively that object for
 * D-Bus it doesn't seem worth creating some random object.)
 *
 * @todo optimize this by only rewriting until the old and new values
 * are at the same alignment. Frequently this should result in only
 * replacing the value that's immediately at hand.
 *
 * @param reader reader indicating where to set a new value
 * @param value address of the value to set
 * @param realign_root realign from here
 * @returns #FALSE if not enough memory

/* Now get type_pos right for the parent writer. Here are the cases:
*

```

```

* Cases !writer->type_pos_is_expectation:
*   (in these cases we want to update to the new insertion point)
*
* - if we recursed into a STRUCT then we didn't know in advance
*   what the types in the struct would be; so we have to fill in
*   that information now.
*     writer->type_pos = sub->type_pos
*
* - if we recursed into anything else, we knew the full array
*   type, or knew the single typecode marking VARIANT, so
*   writer->type_pos is already correct.
*     writer->type_pos should remain as-is
*
* - note that the parent is never an ARRAY or VARIANT, if it were
*   then type_pos_is_expectation would be TRUE. The parent
*   is thus known to be a toplevel or STRUCT.
*
* Cases where writer->type_pos_is_expectation:
*   (in these cases we want to update to next expected type to
write)
*
* - we recursed from STRUCT into STRUCT and we didn't increment
*   type_pos in the parent just to stay consistent with the
*   !writer->type_pos_is_expectation case (though we could
*   special-case this in recurse_struct instead if we wanted)
*     writer->type_pos = sub->type_pos
*
* - we recursed from STRUCT into ARRAY or VARIANT and type_pos
*   for parent should have been incremented already
*     writer->type_pos should remain as-is
*
* - we recursed from ARRAY into a sub-element, so type_pos in the
*   parent is the element type and should remain the element type
*   for the benefit of the next child element
*     writer->type_pos should remain as-is
*
* - we recursed from VARIANT into its value, so type_pos in the
*   parent makes no difference since there's only one value
*   and we just finished writing it and won't use type_pos again
*     writer->type_pos should remain as-is
*
* For all these, DICT_ENTRY is the same as STRUCT

/**
 * Frees all memory allocated internally by libdbus and
 * reverses the effects of dbus_threads_init(). libdbus keeps internal
 * global variables, for example caches and thread locks, and it
 * can be useful to free these internal data structures.
 *
 * dbus_shutdown() does NOT free memory that was returned
 * to the application. It only returns libdbus-internal
 * data structures.
 *
 * You MUST free all memory and release all reference counts
 * returned to you by libdbus prior to calling dbus_shutdown().
 *
 * You can't continue to use any D-Bus objects, such as connections,

```

```

* that were allocated prior to dbus_shutdown(). You can, however,
* start over; call dbus_threads_init() again, create new connections,
* and so forth.
*
* WARNING: dbus_shutdown() is NOT thread safe, it must be called
* while NO other threads are using D-Bus. (Remember, you have to free
* all D-Bus objects and memory before you call dbus_shutdown(), so no
* thread can be using libdbus.)
*
* The purpose of dbus_shutdown() is to allow applications to get
* clean output from memory leak checkers. dbus_shutdown() may also be
* useful if you want to dlopen() libdbus instead of linking to it,
* and want to be able to unload the library again.
*
* There is absolutely no requirement to call dbus_shutdown() - in
fact,
* most applications won't bother and should not feel guilty.
*
* You have to know that nobody is using libdbus in your application's
* process before you can call dbus_shutdown(). One implication of
this
* is that calling dbus_shutdown() from a library is almost certainly
* wrong, since you don't know what the rest of the app is up to.

/* Message Cache
*
* We cache some DBusMessage to reduce the overhead of allocating
* them. In my profiling this consistently made about an 8%
* difference. It avoids the malloc for the message, the malloc for
* the slot list, the malloc for the header string and body string,
* and the associated free() calls. It does introduce another global
* lock which could be a performance issue in certain cases.
*
* For the echo client/server the round trip time goes from around
* .000077 to .000069 with the message cache on my laptop. The sysprof
* change is as follows (numbers are cumulative percentage):
*
* with message cache implemented as array as it is now (0.000069
per):
*   new_empty_header          1.46
*   mutex_lock                0.56   # i.e.
_DBUS_LOCK(message_cache)
*   mutex_unlock              0.25

```

```

*      self                0.41
*      unref                2.24
*      self                0.68
*      list_clear          0.43
*      mutex_lock          0.33      # i.e.
_DBUS_LOCK(message_cache)
*      mutex_unlock        0.25
*
* with message cache implemented as list (0.000070 per roundtrip):
*      new_empty_header    2.72
*      list_pop_first      1.88
*      unref                3.3
*      list_prepend        1.63
*
* without cache (0.000077 per roundtrip):
*      new_empty_header    6.7
*      string_init_preallocated 3.43
*      dbus_malloc         2.43
*      dbus_malloc0        2.59
*
*      unref                4.02
*      string_free         1.82
*      dbus_free           1.63
*      dbus_free           0.71
*
* If you implement the message_cache with a list, the primary reason
* it's slower is that you add another thread lock (on the DBusList
* mempool).

/** @} */

/**
 * @defgroup DbusMessage DbusMessage
 * @ingroup Dbus
 * @brief Message to be sent or received over a #DBusConnection.
 *
 * A DbusMessage is the most basic unit of communication over a
 * DbusConnection. A DbusConnection represents a stream of messages
 * received from a remote application, and a stream of messages
 * sent to a remote application.
 *
 * A message has a message type, returned from
 * dbus_message_get_type(). This indicates whether the message is a
 * method call, a reply to a method call, a signal, or an error reply.
 *
 * A message has header fields such as the sender, destination, method
 * or signal name, and so forth. DbusMessage has accessor functions
for
 * these, such as dbus_message_get_member().
 *
 * Convenience functions dbus_message_is_method_call(),
dbus_message_is_signal(),
 * and dbus_message_is_error() check several header fields at once and
are

```

```

* slightly more efficient than checking the header fields with
individual
* accessor functions.
*
* Finally, a message has arguments. The number and types of arguments
* are in the message's signature header field (accessed with
* dbus_message_get_signature()). Simple argument values are usually
* retrieved with dbus_message_get_args() but more complex values such
* as structs may require the use of #DBusMessageIter.
*
* The D-Bus specification goes into some more detail about header
fields and
* message types.
*
* @{
*/

/**
* @typedef DBusMessage
*
* Opaque data type representing a message received from or to be
* sent to another application.
*/

/**
* Returns the serial of a message or 0 if none has been specified.
* The message's serial number is provided by the application sending
* the message and is used to identify replies to this message.
*
* All messages received on a connection will have a serial provided
* by the remote application.
*
* For messages you're sending, dbus_connection_send() will assign a
* serial and return it to you.

}

/**
 * Appends fields to a message given a variable argument list. The
 * variable argument list should contain the type of each argument
 * followed by the value to append. Appendable types are basic types,
 * and arrays of fixed-length basic types (except arrays of Unix file
 * descriptors). To append variable-length basic types, or any more
 * complex value, you have to use an iterator rather than this
 * function.
 *
 * To append a basic type, specify its type code followed by the

```

```

* address of the value. For example:
*
* @code
*
* dbus_int32_t v_INT32 = 42;
* const char *v_STRING = "Hello World";
* dbus_message_append_args (message,
*                             DBUS_TYPE_INT32, &v_INT32,
*                             DBUS_TYPE_STRING, &v_STRING,
*                             DBUS_TYPE_INVALID);
* @endcode
*
* To append an array of fixed-length basic types (except Unix file
* descriptors), pass in the DBUS_TYPE_ARRAY typecode, the element
* typecode, the address of the array pointer, and a 32-bit integer
* giving the number of elements in the array. So for example: @code
* const dbus_int32_t array[] = { 1, 2, 3 }; const dbus_int32_t
* *v_ARRAY = array; dbus_message_append_args (message,
* DBUS_TYPE_ARRAY, DBUS_TYPE_INT32, &v_ARRAY, 3, DBUS_TYPE_INVALID);
* @endcode
*
* This function does not support arrays of Unix file descriptors. If
* you need those you need to manually recurse into the array.
*
* For Unix file descriptors this function will internally duplicate
* the descriptor you passed in. Hence you may close the descriptor
* immediately after this call.
*
* @warning in C, given "int array[]", "&array == array" (the
* comp.lang.c FAQ says otherwise, but gcc and the FAQ don't agree).
* So if you're using an array instead of a pointer you have to create
* a pointer variable, assign the array to it, then take the address
* of the pointer variable. For strings it works to write
* const char *array = "Hello" and then use &array though.
*
* The last argument to this function must be #DBUS_TYPE_INVALID,
* marking the end of the argument list. If you don't do this
* then libdbus won't know to stop and will read invalid memory.
*
* String/signature/path arrays should be passed in as "const char***
* address_of_array" and "int n_elements"
*
* @todo support DBUS_TYPE_STRUCT and DBUS_TYPE_VARIANT and complex
arrays
*
* @todo If this fails due to lack of memory, the message is hosed and
* you have to start over building the whole message.
*
* @param message the message
* @param first_arg_type type of the first argument
* @param ... value of first argument, list of additional type-value
pairs

/**
 * Gets arguments from a message given a variable argument list. The
 * supported types include those supported by
 * dbus_message_append_args(); that is, basic types and arrays of

```

```

* fixed-length basic types. The arguments are the same as they would
* be for dbus_message_iter_get_basic() or
* dbus_message_iter_get_fixed_array().
*
* In addition to those types, arrays of string, object path, and
* signature are supported; but these are returned as allocated memory
* and must be freed with dbus_free_string_array(), while the other
* types are returned as const references. To get a string array
* pass in "char ***array_location" and "int *n_elements".
*
* Similar to dbus_message_get_fixed_array() this function does not
* support arrays of type DBUS_TYPE_UNIX_FD. If you need to parse
* messages with arrays of Unix file descriptors you need to recurse
* into the array manually.
*
* Unix file descriptors that are read with this function will have
* the FD_CLOEXEC flag set. If you need them without this flag set,
* make sure to unset it with fcntl().
*
* The variable argument list should contain the type of the argument
* followed by a pointer to where the value should be stored. The list
* is terminated with #DBUS_TYPE_INVALID.
*
* Except for string arrays, the returned values are constant; do not
* free them. They point into the #DBusMessage.
*
* If the requested arguments are not present, or do not have the
* requested types, then an error will be set.
*
* If more arguments than requested are present, the requested
* arguments are returned and the extra arguments are ignored.
*
* @todo support DBUS_TYPE_STRUCT and DBUS_TYPE_VARIANT and complex
arrays
*
* @param message the message

/**
 * Reads a basic-typed value from the message iterator.
 * Basic types are the non-containers such as integer and string.
 *
 * The value argument should be the address of a location to store
 * the returned value. So for int32 it should be a "dbus_int32_t*"
 * and for string a "const char**". The returned value is
 * by reference and should not be freed.
 *
 * This call duplicates Unix file descriptors when reading them. It is
 * your job to close them when you don't need them anymore.
 *
 * Unix file descriptors that are read with this function will have
 * the FD_CLOEXEC flag set. If you need them without this flag set,
 * make sure to unset it with fcntl().
 *
 * Be sure you have somehow checked that
 * dbus_message_iter_get_arg_type() matches the type you are
 * expecting, or you'll crash when you try to use an integer as a
 * string or something.
 *
 * To read any container type (array, struct, dict) you will need to
 * recurse into the container with dbus_message_iter_recurse(). If
 * the container is an array of fixed-length values (except Unix file
 * descriptors), you can get all the array elements at once with
 * dbus_message_iter_get_fixed_array(). Otherwise, you have to iterate
 * over the container's contents one value at a time.
 *
 * All basic-typed values are guaranteed to fit in a #DBusBasicValue,
 * so in versions of libdbus that have that type, you can write code
like this:
 *
 * @code
 * DBusBasicValue value;
 * int type;
 * dbus_message_iter_get_basic (&read_iter, &value);
 * type = dbus_message_iter_get_arg_type (&read_iter);
 * dbus_message_iter_append_basic (&write_iter, type, &value);
 * @endcode

```

```

*
* (All D-Bus basic types are either numeric and 8 bytes or smaller,
or
* behave like a string; so in older versions of libdbus,
DBusBasicValue
* can be replaced with union { char *string; unsigned char bytes[8];
},
* for instance.)
*
* @param iter the iterator
* @param value location to store the value

/**
* Reads a block of fixed-length values from the message iterator.
* Fixed-length values are those basic types that are not string-like,
* such as integers, bool, double. The returned block will be from the
* current position in the array until the end of the array.
*
* There is one exception here: although DBUS_TYPE_UNIX_FD is
* considered a 'fixed' type arrays of this type may not be read with
* this function.
*
* The message iter should be "in" the array (that is, you recurse
into the
* array, and then you call dbus_message_iter_get_fixed_array() on the
* "sub-iterator" created by dbus_message_iter_recurse()).
*
* The value argument should be the address of a location to store the
* returned array. So for int32 it should be a "const dbus_int32_t**"
* The returned value is by reference and should not be freed.
*
* This function should only be used if dbus_type_is_fixed() returns
* #TRUE for the element type.
*
* If an array's elements are not fixed in size, you have to recurse
* into the array with dbus_message_iter_recurse() and read the
* elements one by one.
*
* Because the array is not copied, this function runs in constant
* time and is fast; it's much preferred over walking the entire array

/**
 * Appends a block of fixed-length values to an array. The
 * fixed-length types are all basic types that are not string-like. So
 * int32, double, bool, etc. (Unix file descriptors however are not
 * supported.) You must call dbus_message_iter_open_container() to
 * open an array of values before calling this function. You may call
 * this function multiple times (and intermixed with calls to
 * dbus_message_iter_append_basic()) for the same array.
 *
 * The "value" argument should be the address of the array. So for
 * integer, "dbus_int32_t**" is expected for example.
 *
 * @warning in C, given "int array[]", "&array == array" (the
 * comp.lang.c FAQ says otherwise, but gcc and the FAQ don't agree).
 * So if you're using an array instead of a pointer you have to create
 * a pointer variable, assign the array to it, then take the address
 * of the pointer variable.
 * @code
 * const dbus_int32_t array[] = { 1, 2, 3 };
 * const dbus_int32_t *v_ARRAY = array;
 * if (!dbus_message_iter_append_fixed_array (&iter, DBUS_TYPE_INT32,
&v_ARRAY, 3))
 *     fprintf (stderr, "No memory!\n");
 * @endcode
 * For strings it works to write const char *array = "Hello" and then

```

```

* use &array though.
*
* @todo If this fails due to lack of memory, the message is hosed and
* you have to start over building the whole message.
*
* @param iter the append iterator
* @param element_type the type of the array elements
* @param value the address of the array
* @param n_elements the number of elements to append
* @returns #FALSE if not enough memory

/*
 * FIXME when we move the header out of the buffer, that memmoves all
 * buffered messages. Kind of crappy.
 *
 * Also we copy the header and body, which is kind of crappy. To
 * avoid this, we have to allow header and body to be in a single
 * memory block, which is good for messages we read and bad for
 * messages we are creating. But we could move_len() the buffer into
 * this single memory block, and move_len() will just swap the buffers
 * if you're moving the entire buffer replacing the dest string.
 *
 * We could also have the message loader tell the transport how many
 * bytes to read; so it would first ask for some arbitrary number like
 * 256, then if the message was incomplete it would use the
 * header/body len to ask for exactly the size of the message (or
 * blocks the size of a typical kernel buffer for the socket). That
 * way we don't get trailing bytes in the buffer that have to be
 * memmoved. Though I suppose we also don't have a chance of reading a
 * bunch of small messages at once, so the optimization may be stupid.
 *
 * Another approach would be to keep a "start" index into
 * loader->data and only delete it occasionally, instead of after

```

/**
 * Obtains the machine UUID of the machine this process is running on.
 *
 * The returned string must be freed with dbus_free().
 *
 * This UUID is guaranteed to remain the same until the next reboot
 * (unless the sysadmin foolishly changes it and screws themselves).
 * It will usually remain the same across reboots also, but hardware
 * configuration changes or rebuilding the machine could break that.
 *
 * The idea is that two processes with the same machine ID should be
 * able to use shared memory, UNIX domain sockets, process IDs, and
other
 * features of the OS that require both processes to be running
 * on the same OS kernel instance.
 *
 * The machine ID can also be used to create unique per-machine
 * instances. For example, you could use it in bus names or
 * X selection names.
 *
 * The machine ID is preferred over the machine hostname, because
 * the hostname is frequently set to "localhost.localdomain" and
 * may also change at runtime.
 */
```

```

* You can get the machine ID of a remote application by invoking the
* method GetMachineId from interface org.freedesktop.DBus.Peer.
*
* If the remote application has the same machine ID as the one
* returned by this function, then the remote application is on the
* same machine as your application.
*
* The UUID is not a UUID in the sense of RFC4122; the details
* are explained in the D-Bus specification.
*
* @returns a 32-byte-long hex-encoded UUID string, or #NULL if
insufficient memory

.TH dbus\--monitor 1
.SH NAME
dbus\--monitor \-- debug probe to print message bus messages
.SH SYNOPSIS
.PP
.B dbus\--monitor
[\--system | \--session | \--address ADDRESS] [\--profile | \--
monitor]
[watch expressions]

.SH DESCRIPTION

The \fIdbus\--monitor\fP command is used to monitor messages going
through a D\--Bus message bus. See
http://www.freedesktop.org/software/dbus/ for more information about
the big picture.

.PP
There are two well\--known message buses: the systemwide message bus
(installed on many systems as the "messagebus" service) and the
per\--user\--login\--session message bus (started each time a user logs
in).
The \--system and \--session options direct \fIdbus\--monitor\fP to
monitor the system or session buses respectively. If neither is
specified, \fIdbus\--monitor\fP monitors the session bus.

```

.PP
\fIdbus\monitor\fP has two different output modes, the 'classic'\-
style
monitoring mode and profiling mode. The profiling format is a compact
format with a single line per message and microsecond\resolution
timing
information. The \-\-profile and \-\-monitor options select the
profiling
and monitoring output format respectively. If neither is specified,
\fIdbus\monitor\fP uses the monitoring output format.

.PP
In order to get \fIdbus\monitor\fP to see the messages you are
interested
in, you should specify a set of watch expressions as you would expect
to
be passed to the \fIdbus_bus_add_match\fP function.

.PP
The message bus configuration may keep \fIdbus\monitor\fP from seeing
all messages, especially if you run the monitor as a non\root user.

.SH OPTIONS

.TP

.I "\-\-system"

Monitor the system message bus.

.TP

.I "\-\-session"

Monitor the session message bus. (This is the default.)

.TP

.I "\-\-address ADDRESS"

Monitor an arbitrary message bus given at ADDRESS.

.TP

.I "\-\-profile"

Use the profiling output format.

.TP

.I "\-\-monitor"

Use the monitoring output format. (This is the default.)

.SH EXAMPLE

Here is an example of using dbus\monitor to watch for the gnome
typing

monitor to say things

.nf

```
dbus\monitor  
"type='signal',sender='org.gnome.TypingMonitor',interface='org.gnome.T  
ypingMonitor'"
```

.fi

.SH AUTHOR

dbus\-monitor was written by Philip Blundell.
The profiling output mode was added by Olli Salli.

.SH BUGS

Please send bug reports to the D\ -Bus mailing list or bug tracker,
see <http://www.freedesktop.org/software/dbus/>

<refsect1 id='description'><title>DESCRIPTION</title>
<para>The <command>dbus-monitor</command> command is used to monitor
messages going
through a D-Bus message bus. See
```

<http://www.freedesktop.org/software/dbus/> for more information about the big picture.

There are two well-known message buses: the systemwide message bus (installed on many systems as the "messagebus" service) and the per-user-login-session message bus (started each time a user logs in). The `--system` and `--session` options direct `dbus-monitor` to monitor the system or session buses respectively. If neither is specified, `dbus-monitor` monitors the session bus.

`dbus-monitor` has two different output modes, the 'classic'-style monitoring mode and profiling mode. The profiling format is a compact format with a single line per message and microsecond-resolution timing information. The `--profile` and `--monitor` options select the profiling and monitoring output format respectively. If neither is specified, `dbus-monitor` uses the monitoring output format.

In order to get `dbus-monitor` to see the messages you are interested in, you should specify a set of watch expressions as you would expect to be passed to the `dbus_bus_add_match` function.

The message bus configuration may keep `dbus-monitor` from seeing all messages, especially if you run the monitor as a non-root user.

OPTIONS

`--system`

Monitor the system message bus.

dbus\--send \-- Send a message to a message bus

```

.SH SYNOPSIS

.PP

.B dbus\--send

[\fB\--system\fP | \fB\--session\fP]

[\fB\--dest=\fINAME\fP]

[\fB\--print\--reply\fP[\fB=literal\fP]]

[\fB\--reply\--timeout=\fIMSEC\fP]

[\fB\--type=\fITYPE\fP]

\fIOBJECT_PATH\fP \fIINTERFACE\fB.\fIMEMBER\fP [\fICONTENTS\fP ...]

.SH DESCRIPTION

The `\fIdbus\--send\fP` command is used to send a message to a D\--Bus message bus. See <http://www.freedesktop.org/software/dbus/> for more information about the big picture.

.PP

There are two well\--known message buses: the systemwide message bus (installed on many systems as the "messagebus" service) and the per\--user\--login\--session message bus (started each time a user logs in).

The `\fB\--system\fP` and `\fB\--session\fP` options direct `\fBdbus\--send\fP` to send messages to the system or session buses respectively.

If neither is specified, `\fBdbus\--send\fP` sends to the session bus.

.PP

Nearly all uses of `\fBdbus\--send\fP` must provide the `\fB\--dest\fP` argument which is the name of a connection on the bus to send the message to. If

`\fB\--dest\fP` is omitted, no destination is set.

.PP

The object path and the name of the message to send must always be specified. Following arguments, if any, are the message contents (message arguments). These are given as `type\--specified` values and may include containers (arrays, dicts, and variants) as described below.

.nf

```
<contents> ::= <item> | <container> [ <item> | <container>... ]
<item>      ::= <type>:<value>
<container> ::= <array> | <dict> | <variant>
<array>     ::= array:<type>:<value>[,<value>...]
<dict>      ::= dict:<type>:<type>:<key>,<value>[,<key>,<value>...]
<variant>   ::= variant:<type>:<value>
<type>      ::= string | int16 | uint 16 | int32 | uint32 | int64 |
uint64 | double | byte | boolean | objpath
```

.fi

D\bus supports more types than these, but `\fBdbus\send\FP` currently does not. Also, `\fBdbus\send\FP` does not permit empty containers or nested containers (e.g. arrays of variants).

.PP

Here is an example invocation:

.nf

```
dbus\send \-\-dest=org.freedesktop.ExampleName           \\  
    /org/freedesktop/sample/object/name                 \\  
    org.freedesktop.ExampleInterface.ExampleMethod      \\  
    int32:47 string:'hello world' double:65.32          \\  
    array:string:"1st item","next item","last item"     \\  
    dict:string:int32:"one",1,"two",2,"three",3         \\  
    variant:int32:\-8                                    \\  
    objpath:/org/freedesktop/sample/object/name
```

.fi

Note that the interface is separated from a method or signal name by a dot, though in the actual protocol the interface and the interface member are separate fields.

.SH OPTIONS

The following options are supported:

.TP

.BI \-\-dest= NAME

Specify the name of the connection to receive the message.

.TP

.B "\-\-print\reply"

Block for a reply to the message sent, and print any reply received in a human-readable form.

.TP

.B "\-\-print\reply=literal"

Block for a reply to the message sent, and print the body of the reply. If the reply is an object path or a string, it is printed literally, with no punctuation, escape characters etc.

.TP

.BI \-\-reply\timeout= MSEC

Wait for a reply for up to `\fIMSEC\FP` milliseconds.

The default is implementation\(\hydefined, typically 25 seconds.

.TP

.B "\-\-system"

Send to the system message bus.

.TP

.B "\-\-session"

Send to the session message bus. (This is the default.)

.TP

.BI \-\-type= TYPE

Specify `\fBmethod_call\FP` or `\fBsignal\FP` (defaults to `"\fBsignal\FP"`).

<refsect1 id='description'><title>DESCRIPTION</title>
```

The `dbus-send` command is used to send a message to a D-Bus message bus. See <http://www.freedesktop.org/software/dbus/> for more information about the big picture.

There are two well-known message buses: the systemwide message bus (installed on many systems as the "messagebus" service) and the per-user-login-session message bus (started each time a user logs in). The `--system` and `--session` options direct `dbus-send` to send messages to the system or session buses respectively. If neither is specified, `dbus-send` sends to the session bus.

Nearly all uses of `dbus-send` must provide the `--dest` argument which is the name of a connection on the bus to send the message to. If `--dest` is omitted, no destination is set.

The object path and the name of the message to send must always be specified. Following arguments, if any, are the message contents (message arguments). These are given as type-specified values and may include containers (arrays, dicts, and variants) as described below.

```
<literallayout remap='.nf'>
<contents> ::= <item> | <container> [ <item>
| <container>...]
<item> ::= <type>:<value>;
<container> ::= <array> | <dict> | <variant>;
<array> ::=
array:<type>:<value>[,<value>...]
<dict> ::=
dict:<type>:<type>:<key>,<value>[,<key>,<value>...]
<variant> ::= variant:<type>:<value>;
<type> ::= string | int16 | uint 16 | int32 | uint32 |
int64 | uint64 | double | byte | boolean | objpath
</literallayout> <!-- .fi -->
```

D-Bus supports more types than these, but `dbus-send` currently does not. Also, `dbus-send` does not permit empty containers

or nested containers (e.g. arrays of variants).</para>

<para>Here is an example invocation:</para>

<literallayout remap='.nf'>

```
dbus-send --dest=org.freedesktop.ExampleName          \  
          /org/freedesktop/sample/object/name          \  
          org.freedesktop.ExampleInterface.ExampleMethod \  
          int32:47 string:'hello world' double:65.32   \  
          array:string:"1st item","next item","last item" \  
          dict:string:int32:"one",1,"two",2,"three",3   \  
          variant:int32:-8                              \  
          objpath:/org/freedesktop/sample/object/name
```

 */

/* Here's the first paragraph of Peter Gutmann's posting:

The following is my SHA (FIPS 180) code updated to allow use of the
"fixed"
SHA, thanks to Jim Gillogly and an anonymous contributor for the
information on
what's changed in the new version. The fix is a simple change which
involves
adding a single rotate in the initial expansion function. It is
unknown
whether this is an optimal solution to the problem which was
discovered in the
SHA or whether it's simply a bandaid which fixes the problem with a
minimum of
effort (for example the reengineering of a great many Capstone chips).
