/**
 * Unquotes a string as the shell (/bin/sh) would. Only handles
 * quotes; if a string contains file globs, arithmetic operators,
 * variables, backticks, redirections, or other special-to-the-shell
 * features, the result will be different from the result a real shell
 * would produce (the variables, backticks, etc. will be passed

```

```

* through literally instead of being expanded). This function is
* guaranteed to succeed if applied to the result of
* _dbus_shell_quote(). If it fails, it returns %NULL.
* The @quoted_string need not actually contain quoted or
* escaped text; _dbus_shell_unquote() simply goes through the string
and
* unquotes/unescapes anything that the shell would. Both single and
* double quotes are handled, as are escapes including escaped
* newlines. The return value must be freed with dbus_free().
*
* Shell quoting rules are a bit strange. Single quotes preserve the
* literal string exactly. escape sequences are not allowed; not even
* \' - if you want a ' in the quoted text, you have to do something
* like 'foo\'\'bar'. Double quotes allow $, `, ", \, and newline to
* be escaped with backslash. Otherwise double quotes preserve things
* literally.

/* _dbus_shell_parse_argv() does a semi-arbitrary weird subset of the
way
* the shell parses a command line. We don't do variable expansion,
* don't understand that operators are tokens, don't do tilde
expansion,
* don't do command substitution, no arithmetic expansion, IFS gets
ignored,
* don't do filename globs, don't remove redirection stuff, etc.
*
* READ THE UNIX98 SPEC on "Shell Command Language" before changing
* the behavior of this code.
*
* Steps to parsing the argv string:
*
* - tokenize the string (but since we ignore operators,
* our tokenization may diverge from what the shell would do)
* note that tokenization ignores the internals of a quoted
* word and it always splits on spaces, not on IFS even
* if we used IFS. We also ignore "end of input indicator"
* (I guess this is control-D?)
*
* Tokenization steps, from UNIX98 with operator stuff removed,
* are:
*
* 1) "If the current character is backslash, single-quote or
affect
* double-quote (\, ' or ") and it is not quoted, it will
quoted
* quoting for subsequent characters up to the end of the
* text. The rules for quoting are as described in Quoting
* . During token recognition no substitutions will be actually
* performed, and the result token will contain exactly the
* characters that appear in the input (except for newline
* character joining), unmodified, including any embedded or
* enclosing quotes or substitution operators, between the
quote
* mark and the end of the quoted text. The token will not be
* delimited by the end of the quoted field."
*
* 2) "If the current character is an unquoted newline character,
* the current token will be delimited."
*
* 3) "If the current character is an unquoted blank character, any
* token containing the previous character is delimited and the
* current character will be discarded."
*
* 4) "If the previous character was part of a word, the current
* character will be appended to that word."
*
* 5) "If the current character is a "#", it and all subsequent
* characters up to, but excluding, the next newline character
* will be discarded as a comment. The newline character that

```

```

*         ends the line is not considered part of the comment. The
*         "#" starts a comment only when it is at the beginning of a
*         token. Since the search for the end-of-comment does not
*         consider an escaped newline character specially, a comment
*         cannot be continued to the next line."
*
*     6) "The current character will be used as the start of a new
word."
*
*
* - for each token (word), perform portions of word expansion,
namely
*     field splitting (using default whitespace IFS) and quote
*     removal. Field splitting may increase the number of words.
*     Quote removal does not increase the number of words.
*
* "If the complete expansion appropriate for a word results in an
* empty field, that empty field will be deleted from the list of
* fields that form the completely expanded command, unless the
* original word contained single-quote or double-quote characters."
* - UNIX98 spec
*
*

probably
    * free resources in the kernel. When we come to do
socket_set_epoll_enable,
    * there might not be enough resources to bring it back!
    *
    * The next idea you might have is to set the flags to 0. However,
events
    * always trigger on EPOLLERR and EPOLLHUP, even if libdbus isn't
actually
    * delivering them to a DBusWatch. Because epoll is level-triggered
by
    * default, we'll busy-loop on an unhandled error or hangup; not
good.
    *
    * So, let's set it to be edge-triggered: then the worst case is
that
    * we return from poll immediately on one iteration, ignore it
because no
    * watch is enabled, then go back to normal. When we re-enable a
watch
    * we'll switch back to level-triggered and be notified again
(verified to
    * work on 2.6.32). Compile this file with -
DTEST_BEHAVIOUR_OF_EPOLLET for
    * test code.

[Message Bus Overview](#message-bus-overview)

[Message Bus Names](#message-bus-names)

[Message Bus Message Routing](#message-bus-routing)

[Message Bus Starting Services](#message-bus-starting-services)

[Well-known Message Bus Instances](#message-bus-types)

[Message Bus Messages](#message-bus-messages)

[Glossary](#idp5904720)

[Introduction](#)

D-Bus is a system for low-latency, low-overhead, easy to use interprocess communication (IPC). In more detail:

- D-Bus is low-latency because it is designed to avoid round trips and allow asynchronous operation, much like the X protocol.
- D-Bus is low-overhead because it uses a binary protocol, and does not have to convert to and from a text format such as XML. Because D-Bus is intended for potentially high-resolution same-machine IPC, not primarily for Internet IPC, this is an interesting optimization.
- D-Bus is easy to use because it works in terms of messages rather than byte streams, and automatically handles a lot of the hard IPC issues. Also, the D-Bus library is designed to be wrapped in a way that lets developers use their framework's existing object/type system, rather than learning a new one specifically for IPC.

The base D-Bus protocol is a one-to-one (peer-to-peer or client-server) protocol, specified in [the section called “Message Protocol”](#message-protocol "Message Protocol"). That is, it is

a system for one application to talk to a single other application. However, the primary intended application of the protocol is the

D-Bus *message bus*, specified in [the section called "Message Bus Specification"](#). The message bus is a special application that

accepts connections from multiple other applications, and forwards messages among them.

</p><p>

Uses of D-Bus include notification of system changes (notification of when

a camera is plugged in to a computer, or a new version of some software

has been installed), or desktop interoperability, for example a file

monitoring service or a configuration service.

</p><p>

D-Bus is designed for two specific use cases:

</p><div class="itemizedlist"><ul class="itemizedlist" type="disc"><li class="listitem"><p>

A "system bus" for notifications from the system to user sessions,

and to allow the system to request input from user sessions.

</p><li class="listitem"><p>

A "session bus" used to implement desktop environments such as

GNOME and KDE.

</p></div><p>

D-Bus is not intended to be a generic IPC system for any possible

application, and intentionally omits many features found in other

IPC systems for this reason.

</p><p>

At the same time, the bus daemons offer a number of features not found in

other IPC systems, such as single-owner "bus names" (similar to X

selections), on-demand startup of services, and security policies.

In many ways, these features are the primary motivation for developing

D-Bus; other systems would have sufficed if IPC were the only goal.

</p><p>

D-Bus may turn out to be useful in unanticipated applications, but future

versions of this spec and the reference implementation probably will not

incorporate features that interfere with the core use cases.

</p><p>
The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119. However, the document could use a serious audit to be sure it makes sense to do so. Also, they are not capitalized.

</p><div class="sect2" title="Protocol and Specification Stability"><div class="titlepage"><div><div><h3 class="title">Protocol and Specification Stability</h3></div></div></div><p>
The D-Bus protocol is frozen (only compatible extensions are allowed) as of November 8, 2006. However, this specification could still use a fair bit of work to make interoperable reimplementations possible without reference to the D-Bus reference implementation. Thus, this specification is not marked 1.0. To mark it 1.0, we'd like to see someone invest significant effort in clarifying the specification language, and growing the specification to cover more aspects of the reference implementation's behavior.

</p><p>
Until this work is complete, any attempt to reimplement D-Bus will probably require looking at the reference implementation and/or asking questions on the D-Bus mailing list about intended behavior. Questions on the list are very welcome.

</p><p>
Nonetheless, this document should be a useful starting point and is to our knowledge accurate, though incomplete.

</p></div></div><div class="sect1" title="Type System"><div class="titlepage"><div><div><h2 class="title" style="clear: both">Type System</h2></div></div></div><p>
D-Bus has a type system, in which values of various types can be serialized into a sequence of bytes referred to as the <em class="firstterm">wire format in a standard way. Converting a value from some other representation into the wire format is called <em class="firstterm">marshaling and converting it back from the wire format is <em class="firstterm">unmarshaling.

[Type Signatures](#)

The D-Bus protocol does not include type tags in the marshaled data; a block of marshaled values must have a known `type signature`. The type signature is made up of `type codes`. A type code is an ASCII character representing the type of a value. Because ASCII characters are used, the type signature will always form a valid ASCII string. A simple string compare determines whether two type signatures are equivalent.

As a simple example, the type code for 32-bit integer (`INT32`) is the ASCII character 'i'. So the signature for a block of values containing a single `INT32` would be:

```

i
  
```

A block of values containing two `INT32` would have this signature:

```

ii
  
```

All `basic` types work like `INT32` in this example. To marshal and unmarshal basic types, you simply read one value from the data block corresponding to each type code in the signature. In addition to basic types, there are four `container` types: `STRUCT`, `ARRAY`, `VARIANT`, and `DICT_ENTRY`.

`STRUCT` has a type code, ASCII character 'r', but this type code does not appear in signatures. Instead, ASCII characters '(' and ')' are used to mark the beginning and end of the struct. So for example, a struct containing two integers would have this signature:

```

(ii)
  
```

Structs can be nested, so for example a struct containing an integer and another struct:

```

</pre><pre class="programlisting">
    "(i(ii))"
</pre><p>
    The value block storing that struct would contain three integers; the type signature allows you to distinguish "(i(ii))" from "((ii)i)" or "(iii)" or "iii".
</p><p>
    The <code class="literal">STRUCT</code> type code 'r' is not currently used in the D-Bus protocol, but is useful in code that implements the protocol. This type code is specified to allow such code to interoperate in non-protocol contexts.
</p><p>
    Empty structures are not allowed; there must be at least one type code between the parentheses.
</p><p>
    <code class="literal">ARRAY</code> has ASCII character 'a' as type code. The array type code must be followed by a <em class="firstterm">single complete type</em>. The single complete type following the array is the type of each array element. So the simple example is:
</p><pre class="programlisting">
    "ai"
</pre><p>
    which is an array of 32-bit integers. But an array can be of any type, such as this array-of-struct-with-two-int32-fields:
</p><pre class="programlisting">
    "a(ii)"
</pre><p>
    Or this array of array of integer:
</p><pre class="programlisting">
    "aai"
</pre><p>
    The phrase <em class="firstterm">single complete type</em> deserves some definition. A single complete type is a basic type code, a variant type code, an array with its element type, or a struct with its fields. So the following signatures are not single complete types:
</p><pre class="programlisting">
    "aa"
</pre><p>
</pre><pre class="programlisting">

```

```
"(ii"  
</pre><p>  
</p><pre class="programlisting">  
"ii)"  
</pre><p>
```

And the following signatures contain multiple complete types:

```
</p><pre class="programlisting">  
"ii"  
</pre><p>  
</p><pre class="programlisting">  
"aiai"  
</pre><p>  
</p><pre class="programlisting">  
"(ii)(ii)"  
</pre><p>
```

Note however that a single complete type may contain multiple other single complete types.

</p><p>
<code class="literal">VARIANT</code> has ASCII character 'v' as its type code. A marshaled value of type <code class="literal">VARIANT</code> will have the signature of a single complete type as part of the value. This signature will be followed by a marshaled value of that type.

</p><p>
A <code class="literal">DICT_ENTRY</code> works exactly like a struct, but rather than parentheses it uses curly braces, and it has more restrictions.

The restrictions are: it occurs only as an array element type; it has exactly two single complete types inside the curly braces; the first single complete type (the "key") must be a basic type rather than a container type. Implementations must not accept dict entries outside of arrays, must not accept dict entries with zero, one, or more than two fields, and must not accept dict entries with non-basic-typed keys. A dict entry is always a key-value pair.

</p><p>
The first field in the <code class="literal">DICT_ENTRY</code> is always the key.

A message is considered corrupt if the same key occurs twice in the same array of <code class="literal">DICT_ENTRY</code>. However, for performance reasons

implementations are not required to reject dicts with duplicate keys.

</p><p>

In most languages, an array of dict entry would be represented as a

map, hash table, or dict object.

</p><p>

The following table summarizes the D-Bus types.

</p><div class="informaltable"><table border="1"><colgroup><col><col><col></colgroup><thead><tr><th>Conventional Name</th><th>Code</th><th>Description</th></tr></thead><tbody><tr><td><code class="literal">INVALID</code></td><td>0 (ASCII NUL)</td><td>Not a valid type code, used to terminate signatures</td></tr><tr><td><code class="literal">BYTE</code></td><td>121 (ASCII 'y')</td><td>8-bit unsigned integer</td></tr><tr><td><code class="literal">BOOLEAN</code></td><td>98 (ASCII 'b')</td><td>Boolean value, 0 is <code class="literal">FALSE</code> and 1 is <code class="literal">TRUE</code>. Everything else is invalid.</td></tr><tr><td><code class="literal">INT16</code></td><td>110 (ASCII 'n')</td><td>16-bit signed integer</td></tr><tr><td><code class="literal">UINT16</code></td><td>113 (ASCII 'q')</td><td>16-bit unsigned integer</td></tr><tr><td><code class="literal">INT32</code></td><td>105 (ASCII 'i')</td><td>32-bit signed integer</td></tr><tr><td><code class="literal">UINT32</code></td><td>117 (ASCII 'u')</td><td>32-bit unsigned integer</td></tr><tr><td><code class="literal">INT64</code></td><td>120 (ASCII 'x')</td><td>64-bit signed integer</td></tr><tr><td><code class="literal">UINT64</code></td><td>116 (ASCII 't')</td><td>64-bit unsigned integer</td></tr><tr><td><code class="literal">DOUBLE</code></td><td>100 (ASCII 'd')</td><td>IEEE 754 double</td></tr><tr><td><code class="literal">STRING</code></td><td>115 (ASCII 's')</td><td>UTF-8 string (must be valid UTF-8). Must be nul terminated and contain no other nul bytes.</td></tr><tr><td><code class="literal">OBJECT_PATH</code></td><td>111 (ASCII 'o')</td><td>Name of an object instance</td></tr><tr><td><code class="literal">SIGNATURE</code></td><td>103 (ASCII 'g')</td><td>A type signature</td></tr><tr><td><code class="literal">ARRAY</code></td><td>97 (ASCII 'a')</td><td>Array</td></tr><tr><td><code class="literal">STRUCT</code></td><td>114 (ASCII 'r'), 40 (ASCII '('), 41 (ASCII ')')</td><td>Struct; type code 114 'r' is reserved for use in

general bindings and implementations to represent the

concept of a struct, and must not appear in signatures

	used on D-Bus.
<code>VARIANT</code>	118 (ASCII 'v')
Variant type (the type of the value is part of the value itself)	
<code>DICTIONARY_ENTRY</code>	101 (ASCII 'e'), 123 (ASCII '{'), 125 (ASCII '}')
Entry in a dict or map (array of key-value pairs).	
	Type code 101 'e' is reserved for use in bindings and implementations to represent the general concept of a dict or dict-entry, and must not appear in signatures
	used on D-Bus.
<code>UNIX_FD</code>	104 (ASCII 'h')
Unix file descriptor	
	(reserved)
	109 (ASCII 'm')
Reserved for a	
	'maybe' type compatible with the one in <code>GVariant</code> ,
	and must not appear in signatures used on D-Bus until specified
	(reserved)
	42 (ASCII '*')
Reserved for use in bindings/implementations to represent any <i>single complete type</i> ,	
	and must not appear in signatures used on D-Bus.
	(reserved)
	63 (ASCII '?')
Reserved for use in bindings/implementations to represent any <i>basic type</i> ,	
	and must not appear in signatures used on D-Bus.
	(reserved)
	64 (ASCII '@'), 38 (ASCII '&'),
	94 (ASCII '^')
Reserved for internal use by bindings/implementations,	
	and must not appear in signatures used on D-Bus.
<code>GVariant</code> uses these type-codes to encode calling conventions.	

[Marshaling \(Wire Format\)](#)

[Marshaling \(Wire Format\)](#)

Given a type signature, a block of bytes can be converted into typed values. This section describes the format of the block of bytes. Byte order and alignment issues are handled uniformly for all D-Bus types.

A block of bytes has an associated byte order. The byte order has to be discovered in some way; for D-Bus messages, the byte order is part of the message header as described in [the section called "Message Format"](# "Message Format"). For now, assume that the byte order is known to be either little endian or big endian.

Each value in a block of bytes is aligned "naturally," for example 4-byte values are aligned to a 4-byte boundary, and 8-byte values to an 8-byte boundary. To properly align a value, alignment padding may be necessary. The alignment padding must always be the minimum required padding to properly align the following value; and it must always be made up of nul bytes. The alignment padding must not be left uninitialized (it can't contain garbage), and more padding than required must not be used.

Given all this, the types are marshaled on the wire as follows:

Conventional Name	Encoding	Alignment
	<code>INVALID</code>	Not applicable; cannot be marshaled.
	<code>BYTE</code>	A single 8-bit byte.
	<code>BOOLEAN</code>	1
	<code>UINT32</code>	As for <code>UINT16</code> , but only 0 and 1 are valid values.
	<code>INT16</code>	4
	<code>UINT16</code>	16-bit signed integer in the message's byte order.
	<code>INT32</code>	2
	<code>UINT32</code>	16-bit unsigned integer in the message's byte order.
	<code>INT64</code>	32-bit signed integer in the message's byte order.
	<code>UINT64</code>	4
	<code>DOUBLE</code>	32-bit unsigned integer in the message's byte order.
		64-bit signed integer in the message's byte order.
		8
		64-bit IEEE 754 double in the message's byte order.
		8

<pre> class="literal">STRING</code></td><td>A <code class="literal">UINT32</code> indicating the string's length in bytes excluding its terminating nul, followed by a terminating nul byte. </pre>	<pre> </td><td> 4 (for the length) </td></tr><tr><td><code class="literal">OBJECT_PATH</code></td><td>Exactly the same as <code class="literal">STRING</code> except the content must be a valid object path (see below). </td><td> 4 (for the length) </td></tr><tr><td><code class="literal">SIGNATURE</code></td><td>The same as <code class="literal">STRING</code> except the length is a single byte (thus signatures have a maximum length of 255) and the content must be a valid signature (see below). </td><td> 1 </td></tr><tr><td><code class="literal">ARRAY</code></td><td> A <code class="literal">UINT32</code> giving the length of the array data in bytes, followed by alignment padding to the alignment boundary of the array element type, followed by each array element. The array length is from the end of the alignment padding to the end of the last element, i.e. it does not include the padding after the length, or any padding after the last element. Arrays have a maximum length defined to be 2 to the 26th power or 67108864. Implementations must not send or accept arrays exceeding this length. </td><td> 4 (for the length) </td></tr><tr><td><code class="literal">STRUCT</code></td><td> A struct must start on an 8-byte boundary regardless of the type of the struct fields. The struct value consists of each field marshaled in sequence starting from that 8- byte alignment boundary. </pre>
--	--

	8
<code>VARIANT</code>	A variant type has a marshaled
	<code>SIGNATURE</code> followed by a
marshaled	value with the type given in the signature. Unlike
	a message signature, the variant signature can
	contain only a single complete type. So "i", "ai"
may not	or "(ii)" is OK, but "ii" is not. Use of variants
	cause a total message depth to be larger than 64,
including	other container types such as structures.

	1 (alignment of the signature)
<code>DICT_ENTRY</code>	Identical to STRUCT.
	8
<code>UNIX_FD</code>	32-bit unsigned integer in the
message's byte	order. The actual file descriptors need to be
	transferred out-of-band via some platform specific
	mechanism. On the wire, values of this type store the
index to the	file descriptor in the array of file descriptors that
	accompany the
message.	4

</p><div class="sect3" title="Valid Object Paths"><div class="titlepage"><div><div><h4 class="title">Valid Object Paths</h4></div></div></div><p>

An object path is a name used to refer to an object instance. Conceptually, each participant in a D-Bus message exchange may have any number of object instances (think of C++ or Java objects) and each such instance will have a path. Like a filesystem, the object instances in an application form a hierarchical tree.

The following rules define a valid object path. Implementations must not send or accept messages with invalid object paths.

- The path may be of any length.

```

    </p></li><li class="listitem"><p>
        The path must begin with an ASCII '/' (integer 47)
character,
        and must consist of elements separated by slash
characters.
    </p></li><li class="listitem"><p>
        Each element must only contain the ASCII characters
        "[A-Z][a-z][0-9]_"
    </p></li><li class="listitem"><p>
        No element may be the empty string.
    </p></li><li class="listitem"><p>
        Multiple '/' characters cannot occur in sequence.
    </p></li><li class="listitem"><p>
        A trailing '/' character is not allowed unless the
        path is the root path (a single '/' character).
    </p></li></ul></div><p>
</p><p>
    Object paths are often namespaced by starting with a
reversed
    domain name and containing an interface version number, in
the
    same way as
    <a class="link" href="#message-protocol-names-interface"
title="Interface names">interface
    names</a> and
    <a class="link" href="#message-protocol-names-bus"
title="Bus names">well-known
    bus names</a>.
    This makes it possible to implement more than one service,
or
    more than one version of a service, in the same process,
    even if the services share a connection but cannot otherwise
    co-operate (for instance, if they are implemented by
different
    plugins).
    </p><p>
    For instance, if the owner of <code
class="literal">example.com</code> is
    developing a D-Bus API for a music player, they might use
the
    hierarchy of object paths that start with
    <code class="literal">/com/example/MusicPlayer1</code> for
its objects.
    </p></div><div class="sect3" title="Valid Signatures"><div
class="titlepage"><div><div><h4 class="title"><a name="message-
protocol-marshaling-signature"></a>Valid
Signatures</h4></div></div></div><p>
    An implementation must not send or accept invalid
signatures.
    Valid signatures will conform to the following rules:
    </p><div class="itemizedlist"><ul class="itemizedlist"
type="disc"><li class="listitem"><p>

```

```

    The signature ends with a nul byte.
  </p></li><li class="listitem"><p>
    The signature is a list of single complete types.
    Arrays must have element types, and structs must
    have both open and close parentheses.
  </p></li><li class="listitem"><p>
    Only type codes and open and close parentheses are
    allowed in the signature. The <code
class="literal">STRUCT</code> type code
    is not allowed in signatures, because parentheses
    are used instead.
  </p></li><li class="listitem"><p>
    The maximum depth of container type nesting is 32
array type
    codes and 32 open parentheses. This implies that the
maximum
    total depth of recursion is 64, for an "array of array
of array
    of ... struct of struct of struct of ..." where there
are 32
    array and 32 struct.
  </p></li><li class="listitem"><p>
    The maximum length of a signature is 255.
  </p></li><li class="listitem"><p>
    Signatures must be nul-terminated.
  </p></li></ul></div><p>
  </p></div></div></div><div class="sect1" title="Message
Protocol"><div class="titlepage"><div><div><h2 class="title"
style="clear: both"><a name="message-protocol"></a>Message
Protocol</h2></div></div></div><p>
  A <em class="firstterm">message</em> consists of a
  <em class="firstterm">header</em> and a <em
class="firstterm">body</em>. If you
  think of a message as a package, the header is the address, and
the body
  contains the package contents. The message delivery system uses
the header
  information to figure out where to send the message and how to
interpret
  it; the recipient interprets the body of the message.
  </p><p>
  The body of the message is made up of zero or more
  <em class="firstterm">arguments</em>, which are typed values,
such as an
  integer or a byte array.
  </p><p>
  Both header and body use the D-Bus <a class="link" href="#type-
system" title="Type System">type
  system</a> and format for serializing data.
  </p><div class="sect2" title="Message Format"><div
class="titlepage"><div><div><h3 class="title"><a name="message-
protocol-messages"></a>Message Format</h3></div></div></div><p>

```

A message consists of a header and a body. The header is a block of

values with a fixed signature and meaning. The body is a separate block

of values, with a signature specified in the header.

</p><p>

The length of the header must be a multiple of 8, allowing the body to

begin on an 8-byte boundary when storing the entire message in a single

buffer. If the header does not naturally end on an 8-byte boundary

up to 7 bytes of nul-initialized alignment padding must be added.

</p><p>

The message body need not end on an 8-byte boundary.

</p><p>

The maximum length of a message, including header, header alignment padding,

and body is 2 to the 27th power or 134217728. Implementations must not

send or accept messages exceeding this size.

</p><p>

The signature of the header is:

</p><pre class="programlisting">

```
"yyyyyua(yv)"
```

</pre><p>

Written out more readably, this is:

</p><pre class="programlisting">

```
BYTE, BYTE, BYTE, BYTE, UINT32, UINT32, ARRAY of STRUCT of (BYTE,VARIANT)
```

</pre><p>

</p><p>

These values have the following meanings:

</p><div class="informaltable"><table border="1"><colgroup><col><col></colgroup><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>1st <code class="literal">BYTE</code></td><td>Endianness flag; ASCII 'l' for little-endian

or ASCII 'B' for big-endian. Both header and body are

in this endianness.</td></tr><tr><td>2nd <code class="literal">BYTE</code></td><td><em class="firstterm">Message type. Unknown types must be ignored.

Currently-defined types are described below.

</td></tr><tr><td>3rd <code class="literal">BYTE</code></td><td>Bitwise OR of flags. Unknown flags must be ignored. Currently-defined flags are described below.

</td></tr><tr><td>4th <code class="literal">BYTE</code></td><td>Major protocol version of the sending application. If

the major protocol version of the receiving application does not match, the applications will not be able to communicate and the D-Bus connection must be disconnected. The major protocol version for this version of the specification is 1.

1st	<code>UINT32</code>	Length in bytes of the message body, starting from the end of the header. The header ends after its alignment padding to an 8-boundary.
2nd	<code>UINT32</code>	The serial of this message, used as a cookie by the sender to identify the reply corresponding to this request. This must not be zero.
	<code>ARRAY</code>	An array of zero or more <code>STRUCT</code> of (<code>BYTE</code> , <code>VARIANT</code>)

header fields where the byte is the field code, and the variant is the field value. The message type determines which fields are required.

Message types that can appear in the second byte of the header are:

Conventional name	Decimal value	Description
	0	This is an invalid type.
<code>METHOD_CALL</code>	1	Method call.
<code>METHOD_RETURN</code>	2	Method reply with returned data.
<code>ERROR</code>	3	Error reply. If the first argument exists and is a string, it is an error message.
<code>SIGNAL</code>	4	Signal emission.

Flags that can appear in the third byte of the header:

Conventional name	Hex
-------------------	-----

```

value</th><th>Description</th></tr></thead><tbody><tr><td><code
class="literal">NO_REPLY_EXPECTED</code></td><td>0x1</td><td>This
message does not expect method return replies or
        error replies; the reply can be omitted as an
specification        optimization. However, it is compliant with this
harm        to return the reply despite this flag and the only
        from doing so is extra network traffic.
        </td></tr><tr><td><code
class="literal">NO_AUTO_START</code></td><td>0x2</td><td>The bus must
not launch an owner
        for the destination name in response to this
message.
        </td></tr></tbody></table></div><p>
</p><div class="sect3" title="Header Fields"><div
class="titlepage"><div><div><h4 class="title"><a name="message-
protocol-header-fields"></a>Header Fields</h4></div></div></div><p>
        The array at the end of the header contains <em
class="firstterm">header
        fields</em>, where each field is a 1-byte field code
followed
        by a field value. A header must contain the required header
fields for
        its message type, and zero or more of any optional header
add new        fields. Future versions of this protocol specification may
        fields. Implementations must ignore fields they do not
fields;<        understand. Implementations must not invent their own header
        only changes to this specification may introduce new header
fields.
        </p><p>
        Again, if an implementation sees a header field code that it
does not
        expect, it must ignore that field, as it will be part of a
new
        (but compatible) version of this specification. This also
applies
        to known header fields appearing in unexpected messages, for
example: if a signal has a reply serial it must be ignored
spec.        even though it has no meaning as of this version of the
        </p><p>
        However, implementations must not send or accept known
header fields
        with the wrong type stored in the field value. So for
example a
        message with an <code class="literal">INTERFACE</code> field
of type
        <code class="literal">UINT32</code> would be considered
corrupt.

```

</p><p>

Here are the currently-defined header fields:

```
</p><div class="informaltable"><table
border="1"><colgroup><col><col><col><col><col></colgroup><thead><tr><t

class="literal">ERROR</code>, <code
```

<code>METHOD_RETURN</code>				The serial number of the message this message is a reply to. (The serial number is the second <code>UINT32</code> in the header.)
<code>DESTINATION</code>	6			optional The name of the connection this message is intended for.
<code>STRING</code>				Only used in combination with the message bus, see the section called Message Bus Specification .
<code>SENDER</code>	7			optional Unique name of the sending connection.
<code>STRING</code>				The message bus fills in this field so it is reliable; the field is only meaningful in combination with the message bus.
<code>SIGNATURE</code>	8			optional The signature of the message body.
<code>SIGNATURE</code>				If omitted, it is assumed to be the empty signature "" (i.e. the body must be 0-length).
<code>UNIX_FDS</code>	9			optional The number of Unix file descriptors that accompany the message. If omitted, it is assumed that no Unix file descriptors accompany the message. The actual file descriptors need to be transferred via platform specific mechanism out-of-band. They must be sent at the same time as part of the message itself. They may not be sent before the first byte of the message itself is transferred or after the last byte of the message itself.
<code>UNIX_FDS</code>				

Valid Names

The various names in D-Bus messages have some restrictions.

There is a *maximum name length* of 255 which applies to bus names, interfaces, and members.

Interface names

Interfaces have names with type `STRING`, meaning that they must be valid UTF-8. However, there are also some additional restrictions that apply to interface names specifically:

```

    </p><div class="itemizedlist"><ul class="itemizedlist"
type="disc"><li class="listitem"><p>Interface names are composed of 1
or more elements separated by
    a period ('.') character. All elements must contain at
least
    one character.
    </p></li><li class="listitem"><p>Each element must
only contain the ASCII characters
    "[A-Z][a-z][0-9]_" and must not begin with a digit.
    </p></li><li class="listitem"><p>Interface names must
contain at least one '.' (period)
    character (and thus at least two elements).
    </p></li><li class="listitem"><p>Interface names must
not begin with a '.' (period) character.</p></li><li
class="listitem"><p>Interface names must not exceed the maximum name
length.</p></li></ul></div><p>
    </p><p>
    Interface names should start with the reversed DNS domain
name of
    the author of the interface (in lower-case), like interface
names
    in Java. It is conventional for the rest of the interface
name
    to consist of words run together, with initial capital
letters
    on all words ("CamelCase"). Several levels of hierarchy can
be used.
    It is also a good idea to include the major version of the
interface
    in the name, and increment it if incompatible changes are
made;
    this way, a single object can implement several versions of
an
    interface in parallel, if necessary.
    </p><p>
    For instance, if the owner of <code
class="literal">example.com</code> is
    developing a D-Bus API for a music player, they might define
interfaces called <code
class="literal">com.example.MusicPlayer1</code>,
    <code class="literal">com.example.MusicPlayer1.Track</code>
and
    <code
class="literal">com.example.MusicPlayer1.Seekable</code>.
    </p><p>
    D-Bus does not distinguish between the concepts that would
be
    called classes and interfaces in Java: either can be
identified on
    D-Bus by an interface name.

```

Bus names</h4></div></div></div><p>Connections have one or more bus names associated with them. A connection has exactly one bus name that is a <em class="firstterm">unique connection name. The unique connection name remains with the connection for its entire lifetime. A bus name is of type <code class="literal">STRING</code>, meaning that it must be valid UTF-8. However, there are also some additional restrictions that apply to bus names specifically:</p><div class="itemizedlist"><ul class="itemizedlist" type="disc"><li class="listitem"><p>Bus names that start with a colon (':') character are unique connection names. Other bus names are called <em class="firstterm">well-known bus names. </p><li class="listitem"><p>Bus names are composed of 1 or more elements separated by a period ('.') character. All elements must contain at least one character. </p><li class="listitem"><p>Each element must only contain the ASCII characters "[A-Z][a-z][0-9]_". Only elements that are part of a unique connection name may begin with a digit, elements in other bus names must not begin with a digit. </p><li class="listitem"><p>Bus names must contain at least one '.' (period) character (and thus at least two elements). </p><li class="listitem"><p>Bus names must not begin with a '.' (period) character.</p><li class="listitem"><p>Bus names must not exceed the maximum name length.</p></div><p></p><p>Note that the hyphen ('-') character is allowed in bus names but not in interface names. </p><p>Like interface names, well-known bus names should start with the reversed DNS domain name of the author of the interface (in lower-case), and it is conventional for the rest of the well-known bus name to consist of words run together, with initial capital letters. As with interface names, including a version number in well-known bus names is a good idea; it's possible to

have the well-known bus name for more than one version simultaneously if backwards compatibility is required.

</p><p>
If a well-known bus name implies the presence of a "main" interface,
that "main" interface is often given the same name as the well-known bus name, and situated at the corresponding object path. For instance, if the owner of <code class="literal">example.com</code> is developing a D-Bus API for a music player, they might define that any application that takes the well-known name <code class="literal">com.example.MusicPlayer1</code> should have an object at the object path <code class="literal">/com/example/MusicPlayer1</code> which implements the interface <code class="literal">com.example.MusicPlayer1</code>.

</p></div><div class="sect3" title="Member names"><div class="titlepage"><div><div><h4 class="title">Member names</h4></div></div></div><p>Member (i.e. method or signal) names:

</p><div class="itemizedlist"><ul class="itemizedlist" type="disc"><li class="listitem"><p>Must only contain the ASCII characters "[A-Z][a-z][0-9]_" and may not begin with a digit.</p><li class="listitem"><p>Must not contain the '.' (period) character.</p><li class="listitem"><p>Must not exceed the maximum name length.</p><li class="listitem"><p>Must be at least 1 byte in length.</p></div><p></p><p>It is conventional for member names on D-Bus to consist of capitalized words with no punctuation ("camel-case"). Method names should usually be verbs, such as <code class="literal">GetItems</code>, and signal names should usually be a description of an event, such as <code class="literal">ItemsChanged</code>.

</p></div><div class="sect3" title="Error names"><div class="titlepage"><div><div><h4 class="title">Error names</h4></div></div></div><p>Error names have the same restrictions as interface names.

</p><p>Error names have the same naming conventions as interface names, and often contain <code class="literal">.Error.</code>; for instance, the owner of <code class="literal">example.com</code> might define the errors <code class="literal">com.example.MusicPlayer.Error.FileNotFound</code>

and `com.example.MusicPlayer.Error.OutOfMemory`.
The errors defined by D-Bus itself, such as
`org.freedesktop.DBus.Error.Failed`, follow a
similar pattern.

</p></div></div><div class="sect2" title="Message Types"><div
class="titlepage"><div><div><h3 class="title"><a name="message-
protocol-types">Message Types</h3></div></div></div><p>

Each of the message types (`METHOD_CALL`, `METHOD_RETURN`, `ERROR`, and
`SIGNAL`) has its own expected
usage conventions and header fields.

This section describes these conventions.
</p><div class="sect3" title="Method Calls"><div
class="titlepage"><div><div><h4 class="title"><a name="message-
protocol-types-method">Method Calls</h4></div></div></div><p>
Some messages invoke an operation on a remote object. These
are

called method call messages and have the type tag `METHOD_CALL`. Such
messages map naturally to methods on objects in a typical
program.

</p><p>
A method call message is required to have a `MEMBER` header field
indicating the name of the method. Optionally, the message
has an
`INTERFACE` field giving the
interface the method is a part of. In the
absence of an `INTERFACE` field,
if two interfaces on the same object have
a method with the same name, it is undefined which of the
two methods
will be invoked. Implementations may also choose to return
an error in
this ambiguous case. However, if a method name is unique
implementations must not require an interface field.

</p><p>
Method call messages also include a `PATH` field
indicating the object to invoke the method on. If the call
is passing
through a message bus, the message will also have a
`DESTINATION` field giving the
name of the connection
to receive the message.

</p><p>
When an application handles a method call message, it is
required to

return a reply. The reply is identified by a `REPLY_SERIAL` header field

indicating the serial number of the `METHOD_CALL` being replied to. The

reply can have one of two types; either `METHOD_RETURN` or `ERROR`.

If the reply has type `METHOD_RETURN`, the arguments to the reply message

are the return value(s) or "out parameters" of the method call.

If the reply has type `ERROR`, then an "exception" has been thrown,

and the call fails; no return value will be provided. It makes

no sense to send multiple replies to the same method call.

Even if a method call has no return values, a `METHOD_RETURN`

reply is required, so the caller will know the method was successfully processed.

The `METHOD_RETURN` or `ERROR` reply message must have the `REPLY_SERIAL`

header field.

If a `METHOD_CALL` message has the flag `NO_REPLY_EXPECTED`,

then as an optimization the application receiving the method call may choose to omit the reply message (regardless of whether the reply would have been `METHOD_RETURN` or `ERROR`).

However, it is also acceptable to ignore the `NO_REPLY_EXPECTED`

flag and reply anyway.

Unless a message has the flag `NO_AUTO_START`, if the destination name does not exist then a program to own the destination

name will be started before the message is delivered. The message

will be held until the new program is successfully started or has

failed to start; in case of failure, an error will be returned. This

flag is only relevant in the context of a message bus, it is ignored

during one-to-one communication with no intermediate bus.

</p><div class="sect4" title="Mapping method calls to native APIs"><div class="titlepage"><div><div><h5 class="title">Mapping method calls to native APIs</h5></div></div></div><p>

APIs for D-Bus may map method calls to a method call in a specific programming language, such as C++, or may map a method call written in an IDL to a D-Bus message.

</p><p>

In APIs of this nature, arguments to a method are often termed "in" (which implies sent in the <code class="literal">METHOD_CALL</code>), or "out" (which implies returned in the <code class="literal">METHOD_RETURN</code>). Some APIs such as CORBA also have "inout" arguments, which are both sent and received, i.e. the caller passes in a value which is modified. Mapped to D-Bus, an "inout" argument is equivalent to an "in" argument, followed by an "out" argument. You can't pass things "by reference" over the wire, so "inout" is purely an illusion of the in-process API.

</p><p>

Given a method with zero or one return values, followed by zero or more arguments, where each argument may be "in", "out", or "inout", the caller constructs a message by appending each "in" or "inout" argument, in order. "out" arguments are not represented in the caller's message.

</p><p>

The recipient constructs a reply by appending first the return value if any, then each "out" or "inout" argument, in order. "in" arguments are not represented in the reply message.

</p><p>

Error replies are normally mapped to exceptions in languages that have exceptions.

</p><p>

In converting from native APIs to D-Bus, it is perhaps nice to map D-Bus naming conventions ("FooBar") to native conventions such as "fooBar" or "foo_bar" automatically. This is OK as long as you can say that the native API is one that

sense
method,
problem.

was specifically written for D-Bus. It makes the most
when writing object implementations that will be exported
over the bus. Object proxies used to invoke remote D-Bus
objects probably need the ability to call any D-Bus
and thus a magic name mapping like this could be a

bindings;
consistency

</p><p>
This specification doesn't require anything of native API
the preceding is only a suggested convention for
among bindings.

</p></div></div><div class="sect3" title="Signal
Emission"><div class="titlepage"><div><div><h4 class="title">Signal
Emission</h4></div></div></div><p>
Unlike method calls, signal emissions have no replies.
A signal emission is simply a single message of type <code
class="literal">SIGNAL</code>.

It must have three header fields: <code
class="literal">PATH</code> giving the object
the signal was emitted from, plus <code
class="literal">INTERFACE</code> and <code
class="literal">MEMBER</code> giving
the fully-qualified name of the signal. The <code
class="literal">INTERFACE</code> header is required
for signals, though it is optional for method calls.

</p></div><div class="sect3" title="Errors"><div
class="titlepage"><div><div><h4 class="title"><a name="message-
protocol-types-errors">Errors</h4></div></div></div><p>
Messages of type <code class="literal">ERROR</code> are most
commonly replies
to a <code class="literal">METHOD_CALL</code>, but may be
returned in reply
to any kind of message. The message bus for example
will return an <code class="literal">ERROR</code> in reply
to a signal emission if
the bus does not have enough memory to send the signal.

</p><p>
An <code class="literal">ERROR</code> may have any
arguments, but if the first
argument is a <code class="literal">STRING</code>, it must
be an error message.
The error message may be logged or shown to the user
in some way.

</p></div><div class="sect3" title="Notation in this
document"><div class="titlepage"><div><div><h4 class="title">Notation in this
document</h4></div></div></div><p>

This document uses a simple pseudo-IDL to describe particular method calls and signals. Here is an example of a method call:

```
org.freedesktop.DBus.StartServiceByName (in STRING name,
in UINT32 flags,
out UINT32
resultcode)
```

This means `INTERFACE` = `org.freedesktop.DBus`, `MEMBER` = `StartServiceByName`, `METHOD_CALL` arguments are `STRING` and `UINT32`, `METHOD_RETURN` argument is `UINT32`. Remember that the `MEMBER` field can't contain any '.' (period)

characters so it's known that the last part of the name in the "IDL" is the member name.

In C++ that might end up looking like this:

```
unsigned int org::freedesktop::DBus::StartServiceByName
(const char *name,
```

```
unsigned int flags);
or equally valid, the return value could be done as an
argument:
```

```
void org::freedesktop::DBus::StartServiceByName (const
char *name,
unsigned
int flags,
unsigned
int *resultcode);
```

It's really up to the API designer how they want to make this look. You could design an API where the namespace wasn't used in C++, using STL or Qt, using varargs, or whatever you wanted.

Signals are written as follows:

```
org.freedesktop.DBus.NameLost (STRING name)
```

Signals don't specify "in" vs. "out" because only a single direction is possible.

It isn't especially encouraged to use this lame pseudo-IDL in actual API implementations; you might use the native notation for the language you're using, or you might use COM or CORBA IDL, for example.

</p></div></div><div class="sect2" title="Invalid Protocol and Spec Extensions"><div class="titlepage"><div><div><h3 class="title">Invalid Protocol and Spec Extensions</h3></div></div></div><p>

For security reasons, the D-Bus protocol should be strictly parsed and validated, with the exception of defined extension points. Any invalid protocol or spec violations should result in immediately dropping the connection without notice to the other end. Exceptions should be

carefully considered, e.g. an exception may be warranted for a well-understood idiosyncrasy of a widely-deployed implementation. In cases where the other end of a connection is 100% trusted and known to

be friendly, skipping validation for performance reasons could also make sense in certain cases.

</p><p>Generally speaking violations of the "must" requirements in this spec should be considered possible attempts to exploit security, and violations of the "should" suggestions should be considered legitimate (though perhaps they should generate an error in some cases).

</p><p>The following extension points are built in to D-Bus on purpose and must not be treated as invalid protocol. The extension points are intended for use by future versions of this spec, they are not intended for third parties. At the moment, the only way a third party could extend D-Bus without breaking interoperability would be to introduce a way to negotiate new feature support as part of the auth protocol, using EXTENSION_-prefixed commands. There is not yet a standard way to negotiate features.

</p><div class="itemizedlist"><ul class="itemizedlist" type="disc"><li class="listitem"><p>

In the authentication protocol (see [the section called Authentication Protocol](#auth-protocol "Authentication Protocol")) unknown commands result in an ERROR rather than a disconnect.

This enables

future extensions to the protocol. Commands starting with EXTENSION_ are reserved for third parties.

The authentication protocol supports pluggable auth mechanisms.

The address format (see [the section called Server Addresses](#addresses "Server Addresses")) supports new kinds of transport.

Messages with an unknown type (something other than `METHOD_CALL`, `METHOD_RETURN`, `ERROR`, `SIGNAL`) are ignored.

Unknown-type messages must still be well-formed in the same way

as the known messages, however. They still have the normal header and body.

Header fields with an unknown or unexpected field code must be ignored, though again they must still be well-formed.

New standard interfaces (with new methods and signals) can of course be added.

Authentication Protocol

Authentication Protocol

Before the flow of messages begins, two applications must authenticate. A simple plain-text protocol is used for authentication; this protocol is a SASL profile, and maps fairly directly from the SASL specification. The message encoding is NOT used here, only plain text messages.

In examples, "C:" and "S:" indicate lines sent by the client and server respectively.

Protocol Overview

The protocol is a line-based protocol, where each line ends with

\r\n. Each line begins with an all-caps ASCII command name containing only the character range [A-Z_], a space, then any arguments for the command, then the \r\n ending the line. The protocol is case-sensitive. All bytes must be in the ASCII character set.

Commands from the client to the server are as follows:

```
</p><div class="itemizedlist"><ul class="itemizedlist" type="disc"><li class="listitem"><p>AUTH [mechanism] [initial-response]</p></li><li class="listitem"><p>CANCEL</p></li><li class="listitem"><p>BEGIN</p></li><li class="listitem"><p>DATA &lt;data in hex encoding&gt;</p></li><li class="listitem"><p>ERROR [human-readable error explanation]</p></li><li class="listitem"><p>NEGOTIATE_UNIX_FD</p></li></ul></div><p>
```

From server to client are as follows:

```
</p><div class="itemizedlist"><ul class="itemizedlist" type="disc"><li class="listitem"><p>REJECTED &lt;space-separated list of mechanism names&gt;</p></li><li class="listitem"><p>OK &lt;GUID in hex&gt;</p></li><li class="listitem"><p>DATA &lt;data in hex encoding&gt;</p></li><li class="listitem"><p>ERROR</p></li><li class="listitem"><p>AGREE_UNIX_FD</p></li></ul></div><p>
```

Unofficial extensions to the command set must begin with the letters

"EXTENSION_", to avoid conflicts with future official commands.

For example, "EXTENSION_COM_MYDOMAIN_DO_STUFF".

```
</p></div><div class="sect2" title="Special credentials-passing nul byte"><div class="titlepage"><div><div><h3 class="title"><a name="auth-nul-byte"></a>Special credentials-passing nul byte</h3></div></div></div><p>
```

Immediately after connecting to the server, the client must send a single nul byte. This byte may be accompanied by credentials information on some operating systems that use sendmsg() with SCM_CREDS or SCM_CREDENTIALS to pass credentials over UNIX domain sockets. However, the nul byte must be sent even on other kinds of socket, and even on operating systems that do not require a byte to be sent in order to transmit credentials. The text protocol described in this document begins after the single nul byte. If the first byte received from the client is not a nul byte, the server may disconnect that client.

</p><p>
A nul byte in any context other than the initial byte is an
error;
the protocol is ASCII-only.
</p><p>
The credentials sent along with the nul byte may be used with
the
SASL mechanism EXTERNAL.
</p></div><div class="sect2" title="AUTH command"><div
class="titlepage"><div><div><h3 class="title"><a name="auth-command-
auth">AUTH command</h3></div></div></div><p>
If an AUTH command has no arguments, it is a request to list
available mechanisms. The server must respond with a REJECTED
command listing the mechanisms it understands, or with an
error.
</p><p>
If an AUTH command specifies a mechanism, and the server
supports
said mechanism, the server should begin exchanging SASL
challenge-response data with the client using DATA commands.
</p><p>
If the server does not support the mechanism given in the AUTH
command, it must send either a REJECTED command listing the
mechanisms
it does support, or an error.
</p><p>
If the [initial-response] argument is provided, it is intended
for use
with mechanisms that have no initial challenge (or an empty
initial
challenge), as if it were the argument to an initial DATA
command. If
the selected mechanism has an initial challenge and [initial-
response]
was provided, the server should reject authentication by
sending
REJECTED.
</p><p>
If authentication succeeds after exchanging DATA commands,
an OK command must be sent to the client.
</p><p>
The first octet received by the server after the \r\n of the
BEGIN
command from the client must be the first octet of the
authenticated/encrypted stream of D-Bus messages.
</p><p>
If BEGIN is received by the server, the first octet received
by the client after the \r\n of the OK command must be the
first octet of the authenticated/encrypted stream of D-Bus
messages.

</p></div><div class="sect2" title="CANCEL Command"><div class="titlepage"><div><div><h3 class="title">CANCEL Command</h3></div></div></div><p>

At any time up to sending the BEGIN command, the client may send a

CANCEL command. On receiving the CANCEL command, the server must

send a REJECTED command and abort the current authentication exchange.

</p></div><div class="sect2" title="DATA Command"><div class="titlepage"><div><div><h3 class="title">DATA Command</h3></div></div></div><p>

The DATA command may come from either client or server, and simply

contains a hex-encoded block of data to be interpreted according to the SASL mechanism in use.

</p><p>

Some SASL mechanisms support sending an "empty string";

FIXME we need some way to do this.

</p></div><div class="sect2" title="BEGIN Command"><div class="titlepage"><div><div><h3 class="title">BEGIN Command</h3></div></div></div><p>

The BEGIN command acknowledges that the client has received an OK command from the server, and that the stream of messages is about to begin.

</p><p>

The first octet received by the server after the \r\n of the BEGIN

command from the client must be the first octet of the authenticated/encrypted stream of D-Bus messages.

</p></div><div class="sect2" title="REJECTED Command"><div class="titlepage"><div><div><h3 class="title">REJECTED Command</h3></div></div></div><p>

The REJECTED command indicates that the current authentication exchange has failed, and further exchange of DATA is inappropriate.

The client would normally try another mechanism, or try providing

different responses to challenges.

</p><p>

Optionally, the REJECTED command has a space-separated list of available auth mechanisms as arguments. If a server ever provides

a list of supported mechanisms, it must provide the same list each time it sends a REJECTED message. Clients are free to ignore all lists received after the first.

</p></div><div class="sect2" title="OK Command"><div class="titlepage"><div><div><h3 class="title">OK Command</h3></div></div></div><p>

The OK command indicates that the client has been authenticated. The client may now proceed with negotiating Unix file descriptor passing. To do that it shall send

NEGOTIATE_UNIX_FD to the server.

</p><p>

Otherwise, the client must respond to the OK command by sending a BEGIN command, followed by its stream of messages, or by disconnecting. The server must not accept additional commands using this protocol after the BEGIN command has been received. Further communication will be a stream of D-Bus messages (optionally encrypted, as negotiated) rather than this protocol.

</p><p>

If a client sends BEGIN the first octet received by the client after the \r\n of the OK command must be the first octet of the authenticated/encrypted stream of D-Bus messages.

</p><p>

The OK command has one argument, which is the GUID of the server.

See [the section called "Server Addresses" for more on server GUIDs.](#)

</p></div><div class="sect2" title="ERROR Command"><div class="titlepage"><div><div><h3 class="title">ERROR Command</h3></div></div></div><p>

The ERROR command indicates that either server or client did not

know a command, does not accept the given command in the current context, or did not understand the arguments to the command.

This allows the protocol to be extended; a client or server can send a command present or permitted only in new protocol versions, and if an ERROR is received instead of an appropriate response, fall back to using some other technique.

</p><p>

If an ERROR is sent, the server or client that sent the error must continue as if the command causing the ERROR had never been

received. However, the the server or client receiving the error should try something other than whatever caused the error; if only canceling/rejecting the authentication.

</p><p>

If the D-Bus protocol changes incompatibly at some future time, applications implementing the new protocol would probably be able to check for support of the new protocol by sending a new command and receiving an ERROR from applications that don't understand it. Thus the

ERROR feature of the auth protocol is an escape hatch that lets us negotiate extensions or changes to the D-Bus protocol in the future.

</p></div><div class="sect2" title="NEGOTIATE_UNIX_FD Command"><div class="titlepage"><div><div><h3 class="title">NEGOTIATE_UNIX_FD Command</h3></div></div></div><p>

The NEGOTIATE_UNIX_FD command indicates that the client supports Unix file descriptor passing. This command may only be sent after the connection is authenticated, i.e. after OK was received by the client. This command may only be sent on transports that support Unix file descriptor passing.

</p><p>

On receiving NEGOTIATE_UNIX_FD the server must respond with either AGREE_UNIX_FD or ERROR. It shall respond the former if the transport chosen supports Unix file descriptor passing and the server supports this feature. It shall respond the latter if the transport does not support Unix file descriptor passing, the server does not support this feature, or the server decides not to enable file descriptor passing due to security or other reasons.

</p></div><div class="sect2" title="AGREE_UNIX_FD Command"><div class="titlepage"><div><div><h3 class="title">AGREE_UNIX_FD Command</h3></div></div></div><p>

The AGREE_UNIX_FD command indicates that the server supports Unix file descriptor passing. This command may only be sent after the connection is authenticated, and the client sent NEGOTIATE_UNIX_FD to enable Unix file descriptor passing. This command may only be sent on transports that support Unix file descriptor passing.

</p><p>

On receiving AGREE_UNIX_FD the client must respond with BEGIN, followed by its stream of messages, or by disconnecting. The server must not accept additional commands using this protocol after the BEGIN command has been received. Further communication will be a stream of D-Bus messages (optionally encrypted, as negotiated) rather than this protocol.

</p></div><div class="sect2" title="Future Extensions"><div class="titlepage"><div><div><h3 class="title">Future Extensions</h3></div></div></div><p>

Future extensions to the authentication and negotiation protocol are possible. For that new commands may be introduced. If a client or server receives an unknown command it shall respond with ERROR and not consider this fatal. New commands may be introduced both before, and after authentication, i.e. both before and after the OK command.

        </p></div></div><div class="sect2" title="Authentication
mechanisms"><div class="titlepage"><div><div><h3 class="title"><a
name="auth-mechanisms"></a>Authentication
mechanisms</h3></div></div></div><p>
        This section describes some new authentication mechanisms.
        D-Bus also allows any standard SASL mechanism of course.
        </p><div class="sect3" title="DBUS_COOKIE_SHA1"><div
class="titlepage"><div><div><h4 class="title"><a name="auth-
mechanisms-sha"></a>DBUS_COOKIE_SHA1</h4></div></div></div><p>
        The DBUS_COOKIE_SHA1 mechanism is designed to establish that
        a client
        has the ability to read a private file owned by the user
        being

```

authenticated. If the client can prove that it has access to a secret cookie stored in this file, then the client is authenticated.

Thus the security of DBUS_COOKIE_SHA1 depends on a secure home directory.

Throughout this description, "hex encoding" must output the digits from a to f in lower-case; the digits A to F must not be used in the DBUS_COOKIE_SHA1 mechanism.

Authentication proceeds as follows:

- <p><div class="itemizedlist"><ul class="itemizedlist" type="disc"><li class="listitem"><p>

- The client sends the username it would like to authenticate as, hex-encoded.
- The server sends the name of its "cookie context" (see below); a space character; the integer ID of the secret cookie the client must demonstrate knowledge of; a space character; then a randomly-generated challenge string, all of this hex-encoded into one, single string.

- The client locates the cookie and generates its own randomly-generated challenge string. The client then concatenates the server's decoded challenge, a ":" character, its own challenge, another ":" character, and the cookie. It computes the SHA-1 hash of this composite string as a hex digest. It concatenates the client's challenge string, a space character, and the SHA-1 hex digest, hex-encodes the result and sends it back to the server.

- The server generates the same concatenated string used by the client and computes its SHA-1 hash. It compares the hash with the hash received from the client; if the two hashes match, the client is authenticated.

```
</p></li></ul></div><p>
</p><p>
Each server has a "cookie context," which is a name that
identifies a
set of cookies that apply to that server. A sample context
might be
"org_freedesktop_session_bus". Context names must be valid
ASCII,
nonzero length, and may not contain the characters slash
("/"),
backslash ("\\"), space (" "), newline ("\n"), carriage
return ("\r"),
tab ("\t"), or period "."). There is a default context,
"org_freedesktop_general" that's used by servers that do not
specify
otherwise.
</p><p>
Cookies are stored in a user's home directory, in the
directory
<code class="filename">~/.dbus-keyrings/</code>. This
directory must
not be readable or writable by other users. If it is,
clients and servers must ignore it. The directory
contains cookie files named after the cookie context.
</p><p>
A cookie file contains one cookie per line. Each line
has three space-separated fields:
</p><div class="itemizedlist"><ul class="itemizedlist"
type="disc"><li class="listitem"><p>
The cookie ID number, which must be a non-negative
integer and
may not be used twice in the same file.
</p></li><li class="listitem"><p>
The cookie's creation time, in UNIX seconds-since-the-
epoch
format.
</p></li><li class="listitem"><p>
The cookie itself, a hex-encoded random block of
bytes. The cookie
may be of any length, though obviously security
increases
as the length increases.
</p></li></ul></div><p>
</p><p>
Only server processes modify the cookie file.
They must do so with this procedure:
</p><div class="itemizedlist"><ul class="itemizedlist"
type="disc"><li class="listitem"><p>
Create a lockfile name by appending ".lock" to the
name of the
cookie file. The server should attempt to create this
file
```

using `O_CREAT | O_EXCL`.
If file creation fails, the lock fails. Servers should retry for a reasonable period of time, then they may choose to delete an existing lock to keep users from having to manually delete a stale lock. ^{[[1](#ftn.idp5281040)]}

- Once the lockfile has been created, the server loads the cookie file. It should then delete any cookies that are old (the timeout can be fairly short), or more than a reasonable time in the future (so that cookies never accidentally become permanent, if the clock was set far into the future at some point). If no recent keys remain, the server may generate a new key.
- The pruned and possibly added-to cookie file must be resaved atomically (using a temporary file which is `rename()`'d).
- The lock must be dropped by deleting the lockfile.

Clients need not lock the file in order to load it, because servers are required to save the file atomically.

Server Addresses

Server addresses consist of a transport name followed by a colon, and then an optional, comma-separated list of keys and values in the form `key=value`. Each value is escaped.

For example:

```
unix:path=/tmp/dbus-test
```

Which is the address to a unix socket with the path `/tmp/dbus-test`.

Value escaping is similar to URI escaping but simpler.

- The set of optionally-escaped bytes is:

`[0-9A-Za-z_-.]`. To escape, each `byte` (note, not character) which is not in the set of optionally-escaped bytes must be replaced with an ASCII percent (`%`) and the value of the byte in hex. The hex value must always be two digits, even if the first digit is zero. The optionally-escaped bytes may be escaped if desired.

- To unescape, append each byte in the value; if a byte is an ASCII percent (`%`) character then append the following hex value instead. It is an error if a `%` byte does not have two hex digits following. It is an error if a non-optionally-escaped byte is seen unescaped.

The set of optionally-escaped bytes is intended to preserve address readability and convenience.

A server may specify a key-value pair with the key `guid` and the value a hex-encoded 16-byte sequence. [the section called "UUIDs"](#uuids "UUIDs") describes the format of the `guid` field. If present, this UUID may be used to distinguish one server address from another. A server should use a different UUID for each address it listens on. For example, if a message bus daemon offers both UNIX domain socket and TCP connections, but treats clients the same regardless of how they connect, those two connections are equivalent post-connection but should have distinct UUIDs to distinguish the kinds of connection.

The intent of the address UUID feature is to allow a client to avoid opening multiple identical connections to the same server, by allowing the client to check whether an address corresponds to an already-existing

connection. Comparing two addresses is insufficient, because addresses can be recycled by distinct servers, and equivalent addresses may look different if simply compared as strings (for example, the host in a TCP address can be given as an IP address or as a hostname).

Note that the address key is `guid` even though the rest of the API and documentation says "UUID," for historical reasons.

[FIXME clarify if attempting to connect to each is a requirement or just a suggestion]
When connecting to a server, multiple server addresses can be separated by a semi-colon. The library will then try to connect to the first address and if that fails, it'll try to connect to the next one specified, and so forth. For example

```
unix:path=/tmp/dbus-test;unix:path=/tmp/dbus-test2
```

Transports

[FIXME we need to specify in detail each transport and its possible arguments]

Current transports include: unix domain sockets (including abstract namespace on linux), launchd, systemd, TCP/IP, an executed subprocess and a debug/testing transport using in-process pipes. Future possible transports include one that tunnels over X11 protocol.

Unix Domain Sockets

Unix domain sockets can be either paths in the file system or on Linux kernels, they can be abstract which are similar to paths but do not show up in the file system.

When a socket is opened by the D-Bus library it truncates the path name right before the first trailing Nul byte. This is true for both normal paths and abstract paths. Note that this is a departure from previous versions of D-Bus that would create sockets with a fixed length path name. Names which were shorter than the fixed length would be padded by Nul bytes.

Unix domain sockets are not available on Windows.

</p><div class="sect3" title="Server Address Format"><div class="titlepage"><div><div><h4 class="title">Server Address Format</h4></div></div></div><p>

Unix domain socket addresses are identified by the "unix:" prefix

and support the following key/value pairs:

</p><div class="informaltable"><table border="1"><colgroup><col><col><col></colgroup><thead><tr><th>Name</th><th>Values</th><th>Description</th></tr></thead><tbody><tr><td>path</td><td>(path)</td><td>path of the unix domain socket. If set, the "tmpdir" and "abstract" key must not be set.</td></tr><tr><td>tmpdir</td><td>(path)</td><td>temporary directory in which a socket file with a random file name starting with 'dbus-' will be created by the server. This key can only be used in server addresses, not in client addresses. If set, the "path" and "abstract" key must not be set.</td></tr><tr><td>abstract</td><td>(string)</td><td>unique string (path) in the abstract namespace. If set, the "path" or "tmpdir" key must not be set.</td></tr></tbody></table></div></div></div><div class="sect2" title="launchd"><div class="titlepage"><div><div><h3 class="title">launchd</h3></div></div></div><p>

launchd is an open-source server management system that replaces init, inetd

and cron on Apple Mac OS X versions 10.4 and above. It provides a common session

bus address for each user and deprecates the X11-enabled D-Bus launcher on OSX.

</p><p>

launchd allocates a socket and provides it with the unix path through the

DBUS_LAUNCHD_SESSION_BUS_SOCKET variable in launchd's environment. Every process

spawned by launchd (or dbus-daemon, if it was started by launchd) can access

it through its environment.

Other processes can query for the launchd socket by executing:

```
$ launchctl getenv DBUS_LAUNCHD_SESSION_BUS_SOCKET
```

This is normally done by the D-Bus client library so doesn't have to be done

manually.

</p><p>

launchd is not available on Microsoft Windows.

</p><div class="sect3" title="Server Address Format"><div class="titlepage"><div><div><h4 class="title">Server Address Format</h4></div></div></div><p>

launchd addresses are identified by the "launchd:" prefix

and support the following key/value pairs:

</p><div class="informaltable"><table border="1"><colgroup><col><col><col></colgroup><thead><tr><th>Name</th><th>Values</th><th>Description</th></tr></thead><tbody><tr><td>env</td>

d><td>(environment variable)</td><td>path of the unix domain socket for the launchd created dbus-

daemon.</td></tr></tbody></table></div></div></div><div class="sect2" title="systemd"><div class="titlepage"><div><div><h3 class="title">systemd</h3></div></div></div><p>

systemd is an open-source server management system that replaces init and inetd on newer Linux systems. It supports socket activation. The D-Bus systemd transport is used to acquire

socket activation file descriptors from systemd and use them as D-Bus transport when the current process is spawned by socket activation from it.

</p><p>

The systemd transport accepts only one or more Unix domain or TCP streams sockets passed in via socket activation.

</p><p>

The systemd transport is not available on non-Linux operating systems.

</p><p>

The systemd transport defines no parameter keys.

</p></div><div class="sect2" title="TCP Sockets"><div class="titlepage"><div><div><h3 class="title">TCP Sockets</h3></div></div></div><p>

The tcp transport provides TCP/IP based connections between clients

located on the same or different hosts.

</p><p>

Using tcp transport without any additional secure authentication mechanismus

over a network is unsecure.

</p><p>

Windows notes: Because of the tcp stack on Windows does not provide sending

credentials over a tcp connection, the EXTERNAL authentication

mechanismus does not work.

</p><div class="sect3" title="Server Address Format"><div class="titlepage"><div><div><h4 class="title">Server Address Format</h4></div></div></div><p>

TCP/IP socket addresses are identified by the "tcp:" prefix and support the following key/value pairs:

</p><div class="informaltable"><table border="1"><colgroup><col><col><col></colgroup><thead><tr><th>Name</th><th>Values</th><th>Description</th></tr></thead><tbody><tr><td>host</td><td>(string)</td><td>dns name or ip address</td></tr><tr><td>port</td><td>(number)</td><td>The tcp port the server will open. A zero value let the server

choose a free port provided from the underlying operating system.

libdbus is able to retrieve the real used port from the server.

</td></tr><tr><td>family</td><td>(string)</td><td>If set, provide the type of socket family either "ipv4" or "ipv6". If unset, the family is

unspecified.</td></tr></tbody></table></div></div></div><div

class="sect2" title="Nonce-secured TCP Sockets"><div

class="titlepage"><div><div><h3 class="title">Nonce-secured TCP Sockets</h3></div></div></div><p>

The nonce-tcp transport provides a secured TCP transport, using a

simple authentication mechanism to ensure that only clients with read

access to a certain location in the filesystem can connect to the server.

The server writes a secret, the nonce, to a file and an incoming client

connection is only accepted if the client sends the nonce right after

the connect. The nonce mechanism requires no setup and is orthogonal to

the higher-level authentication mechanisms described in the Authentication section.

</p><p>

On start, the server generates a random 16 byte nonce and writes it

to a file in the user's temporary directory. The nonce file location

is published as part of the server's D-Bus address using the "noncefile" key-value pair.

After an accept, the server reads 16 bytes from the socket. If the

read bytes do not match the nonce stored in the nonce file, the

server MUST immediately drop the connection.

If the nonce match the received byte sequence, the client is accepted

and the transport behaves like an unsecured tcp transport.

</p><p>

After a successful connect to the server socket, the client MUST read

the nonce from the file published by the server via the noncefile=

key-value pair and send it over the socket. After that, the transport behaves like an unsecured tcp transport.

</p><div class="sect3" title="Server Address Format"><div class="titlepage"><div><div><h4 class="title">Server Address Format</h4></div></div></div><p>

Nonce TCP/IP socket addresses uses the "nonce-tcp:" prefix and support the following key/value pairs:

Name	Values	Description
host	(string)	dns name or ip address
port	(number)	The tcp port the server will open. A zero value let the server choose a free port provided from the underlying operating system.

libdbus is able to retrieve the real used port from the server.

family	(string)	If set, provide the type of socket family either "ipv4" or "ipv6". If unset, the family is unspecified.
noncefile	(path)	file location containing the secret

Executed Subprocesses on Unix

Executed Subprocesses on Unix

This transport forks off a process and connects its standard input and standard output with an anonymous Unix domain socket. This socket is then used for communication by the transport. This transport may be used to use out-of-process forwarder programs as basis for the D-Bus protocol.

The forked process will inherit the standard error output and process group from the parent process.

Executed subprocesses are not available on Windows.

Server Address Format

Server Address Format

Executed subprocess addresses are identified by the "unixexec:" prefix and support the following key/value pairs:

Name	Values	Description
path	(path)	Path of the binary to execute, either an absolute

path or a binary name that is searched for in the default search path of the OS. This corresponds to the first argument of `execlp()`. This key is mandatory.

argv0	(string)	The program name to use when executing the binary. If omitted the same value as specified for path= will be used. This corresponds to the second argument of <code>execlp()</code> .
argv1, argv2, ...	(string)	Arguments to pass to the binary. This corresponds

to the third and later arguments of `execlp()`. If a

specific argvX is not specified no further argvY for Y
> X

are taken into
account.</td></tr></tbody></table></div></div></div></div><div
class="sect1" title="Meta Transports"><div
class="titlepage"><div><div><h2 class="title" style="clear: both">Meta Transports</h2></div></div></div><p>

Meta transports are a kind of transport with special
enhancements or
behavior. Currently available meta transports include:
autolaunch

</p><div class="sect2" title="Autolaunch"><div
class="titlepage"><div><div><h3 class="title"><a name="meta-
transports-autolaunch">Autolaunch</h3></div></div></div><p>The
autolaunch transport provides a way for dbus clients to autodetect
a running dbus session bus and to autolaunch a session bus if
not present.

</p><div class="sect3" title="Server Address Format"><div
class="titlepage"><div><div><h4 class="title"><a name="meta-
transports-autolaunch-addresses">Server Address
Format</h4></div></div></div><p>

type="disc"><li class="listitem"><p>

"*install-path" - limit session bus to dbus
installation path.

The dbus installation path is determined from the
location of
the shared dbus library. If the library is located in a
'bin'
subdirectory the installation root is the directory
above,
otherwise the directory where the library lives is
taken as

installation root.
</p><pre class="programlisting">
 <lt;install-root>/bin/[lib]dbus-1.dll
 <lt;install-root>/[lib]dbus-1.dll
</pre><p>
</p><li class="listitem"><p>
 "*user" - limit session bus to the recent user.
</p><li class="listitem"><p>
 other values - specify dedicated session bus like

"release",
 "debug" or other
</p></div>

On start, the server opens a platform specific transport, creates a mutex and a shared memory section containing the related session bus address.

This mutex will be inspected by the dbus client library to detect a

running dbus session bus. The access to the mutex and the shared memory section are protected by global locks.

In the recent implementation the autolaunch transport uses a tcp transport

on localhost with a port choosen from the operating system. This detail may

change in the future.

Disclaimer: The recent implementation is in an early state and may not

work in all cirumstances and/or may have security issues.

Because of this

the implementation is not documentated yet.

UUIDs

A working D-Bus implementation uses universally-unique IDs in two places.

First, each server address has a UUID identifying the address, as described in [the section called "Server Addresses"](#).

Second, each operating

system kernel instance running a D-Bus client or server has a UUID

identifying that kernel, retrieved by invoking the method `org.freedesktop.DBus.Peer.GetMachineId()` (see [the section called "org.freedesktop.DBus.Peer"](#) the `org.freedesktop.DBus.Peer`).

The term "UUID" in this document is intended literally, i.e. an identifier that is universally unique. It is not intended to refer to

RFC4122, and in fact the D-Bus UUID is not compatible with that RFC.

The UUID must contain 128 bits of data and be hex-encoded. The hex-encoded string may not contain hyphens or other non-hex-digit

characters, and it must be exactly 32 characters long. To generate a UUID, the current reference implementation concatenates 96 bits of random data followed by the 32-bit time in seconds since the UNIX epoch (in big endian byte order).

It would also be acceptable and probably better to simply generate 128 bits of random data, as long as the random number generator is of high quality. The timestamp could conceivably help if the random bits are not very random. With a quality random number generator, collisions are extremely unlikely even with only 96 bits, so it's somewhat academic.

Implementations should, however, stick to random data for the first 96 bits of the UUID.

</p></div><div class="sect1" title="Standard Interfaces"><div class="titlepage"><div><div><h2 class="title" style="clear: both">Standard Interfaces</h2></div></div></div><p>

See the section called “Notation in this document” for details on

the notation used in this section. There are some standard interfaces that may be useful across various D-Bus applications.

</p><div class="sect2" title="org.freedesktop.DBus.Peer"><div class="titlepage"><div><div><h3 class="title"><code class="literal">org.freedesktop.DBus.Peer</code></h3></div></div></div><p>

The <code class="literal">org.freedesktop.DBus.Peer</code> interface

has two methods:

```
org.freedesktop.DBus.Peer.Ping ()
org.freedesktop.DBus.Peer.GetMachineId (out STRING
machine_uuid)
```

On receipt of the <code class="literal">METHOD_CALL</code> message

<code class="literal">org.freedesktop.DBus.Peer.Ping</code>, an application should do nothing other than reply with a <code class="literal">METHOD_RETURN</code> as

usual. It does not matter which object path a ping is sent to. The

reference implementation handles this method automatically.

On receipt of the `METHOD_CALL` message

`org.freedesktop.DBus.Peer.GetMachineId`, an application should

reply with a `METHOD_RETURN` containing a hex-encoded

UUID representing the identity of the machine the process is running on.

This UUID must be the same for all processes on a single system at least

until that system next reboots. It should be the same across reboots

if possible, but this is not always possible to implement and is not

guaranteed.

It does not matter which object path a `GetMachineId` is sent to. The

reference implementation handles this method automatically.

The UUID is intended to be per-instance-of-the-operating-system, so may represent

a virtual machine running on a hypervisor, rather than a physical machine.

Basically if two processes see the same UUID, they should also see the same

shared memory, UNIX domain sockets, process IDs, and other features that require

a running OS kernel in common between the processes.

The UUID is often used where other programs might use a hostname. Hostnames

can change without rebooting, however, or just be "localhost" - so the UUID

is more robust.

[the section called "UUIDs" explains the format of the UUID.](#)

`org.freedesktop.DBus.Introspectable`

This interface has one method:

```
org.freedesktop.DBus.Introspectable.Introspect (out STRING
```

```
xml_data)
```

```

    </pre><p>
  </p><p>
    Objects instances may implement
    <code class="literal">Introspect</code> which returns an XML
description of
    the object, including its interfaces (with signals and
methods), objects
    below it in the object path tree, and its properties.
  </p><p>
    <a class="xref" href="#introspection-format"
title="Introspection Data Format">the section called
&#8220;Introspection Data Format&#8221;</a> describes the format of
this XML string.
    </p></div><div class="sect2"
title="org.freedesktop.DBus.Properties"><div
class="titlepage"><div><div><h3 class="title"><a name="standard-
interfaces-properties"></a><code
class="literal">org.freedesktop.DBus.Properties</code></h3></div></div
></div><p>
    Many native APIs will have a concept of object <em
class="firstterm">properties</em>
    or <em class="firstterm">attributes</em>. These can be exposed
via the
    <code class="literal">org.freedesktop.DBus.Properties</code>
interface.
  </p><p>
    </p><pre class="programlisting">
      org.freedesktop.DBus.Properties.Get (in STRING
interface_name,
                                      in STRING
property_name,
                                      out VARIANT value);
      org.freedesktop.DBus.Properties.Set (in STRING
interface_name,
                                      in STRING
property_name,
                                      in VARIANT value);
      org.freedesktop.DBus.Properties.GetAll (in STRING
interface_name,
                                      out
DICT<lt;STRING,VARIANT> props);
    </pre><p>
  </p><p>
    It is conventional to give D-Bus properties names consisting
of
    capitalized words without punctuation ("CamelCase"), like
    <a class="link" href="#message-protocol-names-member"
title="Member names">member names</a>.
    For instance, the GObject property
    <code class="literal">connection-status</code> or the Qt
property

```

`connectionStatus` could be represented on D-Bus as `ConnectionStatus`.

Strictly speaking, D-Bus property names are not required to follow the same naming restrictions as member names, but D-Bus property names that would not be valid member names (in particular, GObject-style dash-separated property names) can cause interoperability problems and should be avoided.

The available properties and whether they are writable can be determined by calling `org.freedesktop.DBus.Introspectable.Introspect`, see [the section called `org.freedesktop.DBus.Introspectable`](#).

An empty string may be provided for the interface name; in this case, if there are multiple properties on an object with the same name, the results are undefined (picking one by according to an arbitrary deterministic rule, or returning an error, are the reasonable possibilities).

If one or more properties change on an object, the `org.freedesktop.DBus.Properties.PropertiesChanged` signal may be emitted (this signal was added in 0.14):

```
org.freedesktop.DBus.Properties.PropertiesChanged
(String interface_name,
 DICT<String,Variant> changed_properties,
 ARRAY<String> invalidated_properties);
```

where `changed_properties` is a dictionary containing the changed properties with the new values and `invalidated_properties` is an array of properties that changed but the value is not conveyed.

Whether the `PropertiesChanged` signal is supported can be determined by calling `org.freedesktop.DBus.Introspectable.Introspect`. Note that the signal may be supported for an object but it may differ how whether and how it is used on a per-property basis (for e.g. performance or security reasons). Each property (or the parent interface) must be annotated with the `org.freedesktop.DBus.Property.EmitsChangedSignal` annotation to convey this (usually the default value `true` is sufficient meaning that the annotation does not need to be used). See [the section called "Introspection Data Format"](#introspection-format "Introspection Data Format") for details on this annotation.

`org.freedesktop.DBus.ObjectManager`

`org.freedesktop.DBus.ObjectManager`

An API can optionally make use of this interface for one or more sub-trees of objects. The root of each sub-tree implements this interface so other applications can get all objects, interfaces and properties in a single method call. It is appropriate to use this interface if users of the tree of objects are expected to be interested in all interfaces of all objects in the tree; a more granular API should be used if users of the objects are expected to be interested in a small subset of the objects, a small subset of their interfaces, or both.

The method that applications can use to get all objects and properties is `GetManagedObjects`:

```
org.freedesktop.DBus.ObjectManager.GetManagedObjects (out
DICT<OBJPATH, DICT<STRING, DICT<STRING, VARIANT>>>>
objpath_interfaces_and_properties);
```

The return value of this method is a dict whose keys are object paths. All returned object paths are children of the object path implementing this interface, i.e. their object

paths start with the ObjectManager's object path plus '/'.
 </p><p>
 Each value is a dict whose keys are interfaces names. Each value in this inner dict is the same dict that would be returned by the org.freedesktop.DBus.Properties.GetAll() method for that combination of object path and interface. If an interface has no properties, the empty dict is returned.

</p><p>
 Changes are emitted using the following two signals:

</p><p>
 </p><pre class="programlisting">
 org.freedesktop.DBus.ObjectManager.InterfacesAdded (OBJPATH
 object_path,
 DICT<STRING,DICT<STRING,VARIANT>>
 interfaces_and_properties);
 org.freedesktop.DBus.ObjectManager.InterfacesRemoved
 (OBJPATH object_path,
 ARRAY<STRING> interfaces);
 </pre><p>
 </p><p>
 The <code class="literal">InterfacesAdded</code> signal is emitted when either a new object is added or when an existing object gains one or more interfaces. The <code class="literal">InterfacesRemoved</code> signal is emitted whenever an object is removed or it loses one or more interfaces. The second parameter of the <code class="literal">InterfacesAdded</code> signal contains a dict with the interfaces and properties (if any) that have been added to the given object path. Similarly, the second parameter of the <code class="literal">InterfacesRemoved</code> signal contains an array of the interfaces that were removed. Note that changes on properties on existing interfaces are not reported using this interface - an application should also monitor the existing PropertiesChanged signal on each object.

</p><p>
 Applications SHOULD NOT export objects that are children of an object (directly or otherwise) implementing this interface but which are not returned in the reply from the <code class="literal">GetManagedObjects()</code> method of this interface on the given object.

```

</p><p>
    The intent of the class="literal">ObjectManager</code>
interface
    is to make it easy to write a robust client
    implementation. The trivial client implementation only needs
    to make two method calls:
</p><p>
    </pre><pre class="programlisting">
        org.freedesktop.DBus.AddMatch (bus_proxy,
"type='signal',name='org.example.App',path_namespace='/org/example/App
'");
        objects =
org.freedesktop.DBus.ObjectManager.GetManagedObjects (app_proxy);
    </pre><p>
</p><p>
    on the message bus and the remote application's
    class="literal">ObjectManager</code>, respectively.
Whenever a new
    remote object is created (or an existing object gains a new
    interface), the class="literal">InterfacesAdded</code>
signal is
    emitted, and since this signal contains all properties for the
    interfaces, no calls to the
    class="literal">org.freedesktop.Properties</code>
interface on the
    remote object are needed. Additionally, since the initial
    class="literal">AddMatch()</code> rule already includes
signal
    messages from the newly created child object, no new
    class="literal">AddMatch()</code> call is needed.
</p><p>
    <span class="emphasis"><em>
        The 
class="literal">org.freedesktop.DBus.ObjectManager</code>
        interface was added in version 0.17 of the D-Bus
        specification.
    </em></span>
</p></div></div><div class="sect1" title="Introspection Data
Format"><div class="titlepage"><div><div><h2 class="title"
style="clear: both"><a name="introspection-format"></a>Introspection
Data Format</h2></div></div></div><p>
    As described in <a class="xref" href="#standard-interfaces-
introspectable" title="org.freedesktop.DBus.Introspectable">the
section called &#8220;<code
class="literal">org.freedesktop.DBus.Introspectable</code>&#8221;</a>,
    objects may be introspected at runtime, returning an XML string
    that describes the object. The same XML format may be used in
    other contexts as well, for example as an "IDL" for generating
    static language bindings.
</p><p>
    Here is an example of introspection data:

```

```

</p><pre class="programlisting">
  <!--DOCTYPE node PUBLIC "-//freedesktop//DTD D-BUS Object
  Introspection 1.0//EN"
"http://www.freedesktop.org/standards/dbus/1.0/introspect.dtd">
  <!--node name="/org/freedesktop/sample_object">
  <!--interface name="org.freedesktop.SampleInterface">
  <!--method name="Frobate">
    <!--arg name="foo" type="i" direction="in"/>
    <!--arg name="bar" type="s" direction="out"/>
    <!--arg name="baz" type="a{us}" direction="out"/>
    <!--annotation name="org.freedesktop.DBus.Deprecated"
value="true"/>
  <!--/method>
  <!--method name="Bazify">
    <!--arg name="bar" type="(iiu)" direction="in"/>
    <!--arg name="bar" type="v" direction="out"/>
  <!--/method>
  <!--method name="Mogrify">
    <!--arg name="bar" type="(iiav)" direction="in"/>
  <!--/method>
  <!--signal name="Changed">
    <!--arg name="new_value" type="b"/>
  <!--/signal>
  <!--property name="Bar" type="y" access="readwrite"/>
  <!--/interface>
  <!--node name="child_of_sample_object"/>
  <!--node name="another_child_of_sample_object"/>
  <!--/node>
</pre><p>
</p><p>

```

A more formal DTD and spec needs writing, but here are some quick notes.

```

</p><div class="itemizedlist"><ul class="itemizedlist"
type="disc"><li class="listitem"><p>
  Only the root <!--node> element can omit the node name,
as it's
  known to be the object that was introspected. If the root
  <!--node> does have a name attribute, it must be an
absolute
  object path. If child <!--node> have object paths, they
must be
  relative.
</p></li><li class="listitem"><p>
  If a child <!--node> has any sub-elements, then they
  must represent a complete introspection of the child.
  If a child <!--node> is empty, then it may or may
  not have sub-elements; the child must be introspected
  in order to find out. The intent is that if an object
  knows that its children are "fast" to introspect
  it can go ahead and return their information, but
  otherwise it can omit it.

```

```

</p></li><li class="listitem"><p>
    The direction element on <code>arg</code> may be omitted,
    in which case it defaults to "in" for method calls
    and "out" for signals. Signals only allow "out"
    so while direction may be specified, it's pointless.
</p></li><li class="listitem"><p>
    The possible directions are "in" and "out",
    unlike CORBA there is no "inout"
</p></li><li class="listitem"><p>
    The possible property access flags are
    "readwrite", "read", and "write"
</p></li><li class="listitem"><p>
    Multiple interfaces can of course be listed for
    one <code>node</code>.
</p></li><li class="listitem"><p>
    The "name" attribute on arguments is optional.
</p></li></ul></div><p>

```

```

</p><p>

```

Method, interface, property, and signal elements may have "annotations", which are generic key/value pairs of metadata. They are similar conceptually to Java's annotations and C# attributes.

Well-known annotations:

```

</p><div class="informaltable"><table
border="1"><colgroup><col><col><col></colgroup><thead><tr><th>Name</th>
<th>Values (separated by
,)</th><th>Description</th></tr></thead><tbody><tr><td>org.freedesktop
.DBus.Deprecated</td><td>true,false</td><td>Whether or not the entity
is deprecated; defaults to
false</td></tr><tr><td>org.freedesktop.DBus.GLib.CSymbol</td><td>(stri
ng)</td><td>The C symbol; may be used for methods and
interfaces</td></tr><tr><td>org.freedesktop.DBus.Method.NoReply</td><t
d>true,false</td><td>If set, don't expect a reply to the method call;
defaults to
false.</td></tr><tr><td>org.freedesktop.DBus.Property.EmitsChangedSign
al</td><td>true,invalidates,false</td><td>

```

```

<p>

```

```

    If set to <code class="literal">false</code>, the
<code
class="literal">org.freedesktop.DBus.Properties.PropertiesChanged</cod
e>

```

```

    signal, see <a class="xref" href="#standard-
interfaces-properties" title="org.freedesktop.DBus.Properties">the
section called &#8220;<code
class="literal">org.freedesktop.DBus.Properties</code>&#8221;</a> is
not

```

```

    guaranteed to be emitted if the property changes.
</p>

```

```

<p>

```

```

    If set to <code class="literal">invalidates</code>
the signal
    is emitted but the value is not included in the

```

```

        signal.
    </p>
    <p>
        If set to true the
signal is
        emitted with the value included.
    </p>
    <p>
        The value for the annotation defaults to
        true if the enclosing
interface
        element does not specify the annotation. Otherwise it
        defaults to the value specified in the enclosing
        interface element.
    </p>
</td></tr></tbody></table></div></div><div class="sect1"
title="Message Bus Specification"><div class="titlepage"><div><div><h2
class="title" style="clear: both"><a name="message-bus"></a>Message
Bus Specification</h2></div></div></div><div class="sect2"
title="Message Bus Overview"><div class="titlepage"><div><div><h3
class="title"><a name="message-bus-overview"></a>Message Bus
Overview</h3></div></div></div><p>
    The message bus accepts connections from one or more
applications.
    Once connected, applications can exchange messages with other
    applications that are also connected to the bus.
</p><p>
    In order to route messages among connections, the message bus
keeps a
    mapping from names to connections. Each connection has one
    unique-for-the-lifetime-of-the-bus name automatically
assigned.
    Applications may request additional names for a connection.
Additional
    names are usually "well-known names" such as
    "org.freedesktop.TextEditor". When a name is bound to a
connection,
    that connection is said to own the
name.
</p><p>
    The bus itself owns a special name, org.freedesktop.DBus.
    This name routes messages to the bus, allowing applications to
make
    administrative requests. For example, applications can ask the
bus
    to assign a name to a connection.
</p><p>
    Each name may have queued owners.
When an
    application requests a name for a connection and the name is
already in

```

use, the bus will optionally add the connection to a queue waiting for the name. If the current owner of the name disconnects or releases the name, the next connection in the queue will become the new owner.

</p><p>

This feature causes the right thing to happen if you start two text

editors for example; the first one may request "org.freedesktop.TextEditor",

and the second will be queued as a possible owner of that name. When

the first exits, the second will take over.

</p><p>

Applications may send <em class="firstterm">unicast messages to

a specific recipient or to the message bus itself, or <em class="firstterm">broadcast messages to all interested recipients.

See the section called “Message Bus Message Routing” for details.

</p></div><div class="sect2" title="Message Bus Names"><div class="titlepage"><div><div><h3 class="title">Message Bus Names</h3></div></div></div><p>

Each connection has at least one name, assigned at connection time and

returned in response to the <code class="literal">org.freedesktop.DBus.Hello</code> method call. This

automatically-assigned name is called the connection's <em class="firstterm">unique

name. Unique names are never reused for two different connections to the same bus.

</p><p>

Ownership of a unique name is a prerequisite for interaction with

the message bus. It logically follows that the unique name is always

the first name that an application comes to own, and the last one that it loses ownership of.

</p><p>

Unique connection names must begin with the character ':' (ASCII colon

character); bus names that are not unique names must not begin with this character. (The bus must reject any attempt by an application

to manually request a name beginning with ':'.) This restriction

categorically prevents "spoofing"; messages sent to a unique name

will always go to the expected connection.

When a connection is closed, all the names that it owns are deleted (or transferred to the next connection in the queue if any).

A connection can request additional names to be associated with it using the `org.freedesktop.DBus.RequestName` message. [the section called “Bus names”](#) describes the format of a valid name. These names can be released again using the `org.freedesktop.DBus.ReleaseName` message.

[org.freedesktop.DBus.RequestName](#)

As a method:

```

UINT32 RequestName (in STRING name, in UINT32 flags)

```

Message arguments:

Argument	Type	Description
0	STRING	Name to request
1	UINT32	Flags

Reply arguments:

Argument	Type	Description
0	UINT32	Return value

This method call should be sent to `org.freedesktop.DBus` and asks the message bus to assign the given name to the method caller. Each name maintains a queue of possible owners, where the head of the queue is the primary or current owner of the name. Each potential owner in the queue maintains the `DBUS_NAME_FLAG_ALLOW_REPLACEMENT` and `DBUS_NAME_FLAG_DO_NOT_QUEUE` settings from its latest `RequestName` call. When `RequestName` is invoked the following occurs:

```
</p><div class="itemizedlist"><ul class="itemizedlist"
type="disc"><li class="listitem"><p>
    If the method caller is currently the primary owner of
the name,
    the DBUS_NAME_FLAG_ALLOW_REPLACEMENT and
DBUS_NAME_FLAG_DO_NOT_QUEUE
    values are updated with the values from the new
RequestName call,
    and nothing further happens.
</p></li><li class="listitem"><p>
    If the current primary owner (head of the queue) has
DBUS_NAME_FLAG_ALLOW_REPLACEMENT set, and the
RequestName
    invocation has the DBUS_NAME_FLAG_REPLACE_EXISTING
flag, then
    the caller of RequestName replaces the current primary
owner at
    the head of the queue and the current primary owner
moves to the
    second position in the queue. If the caller of
RequestName was
    in the queue previously its flags are updated with the
values from
    the new RequestName in addition to moving it to the
head of the queue.
</p></li><li class="listitem"><p>
    If replacement is not possible, and the method caller
is
    currently in the queue but not the primary owner, its
flags are
    updated with the values from the new RequestName call.
</p></li><li class="listitem"><p>
    If replacement is not possible, and the method caller
is
    currently not in the queue, the method caller is
appended to the
    queue.
</p></li><li class="listitem"><p>
    If any connection in the queue has
DBUS_NAME_FLAG_DO_NOT_QUEUE
    set and is not the primary owner, it is removed from
the
    queue. This can apply to the previous primary owner
(if it
    was replaced) or the method caller (if it updated the
DBUS_NAME_FLAG_DO_NOT_QUEUE flag while still stuck in
the
    queue, or if it was just added to the queue with that
flag set).
</p></li></ul></div><p>
</p><p>
```

Note that `DBUS_NAME_FLAG_REPLACE_EXISTING` results in "jumping the queue," even if another application already in the queue had specified `DBUS_NAME_FLAG_REPLACE_EXISTING`. This comes up if a primary owner that does not allow replacement goes away, and the next primary owner does allow replacement. In this case, queued items that specified `DBUS_NAME_FLAG_REPLACE_EXISTING` *do not* automatically replace the new primary owner. In other words, `DBUS_NAME_FLAG_REPLACE_EXISTING` is not saved, it is only used at the time `RequestName` is called. This is deliberate to avoid an infinite loop anytime two applications are both `DBUS_NAME_FLAG_ALLOW_REPLACEMENT` and `DBUS_NAME_FLAG_REPLACE_EXISTING`.

The flags argument contains any of the following values logically ORed together:

Conventional Name	Value	Description
<code>DBUS_NAME_FLAG_ALLOW_REPLACEMENT</code>	0x1	

If an application A specifies this flag and succeeds in becoming the owner of the name, and another application B later calls `RequestName` with the `DBUS_NAME_FLAG_REPLACE_EXISTING` flag, then application A will lose ownership and receive a `org.freedesktop.DBus.NameLost` signal, and application B will become the new owner. If `DBUS_NAME_FLAG_ALLOW_REPLACEMENT` is not specified by application A, or `DBUS_NAME_FLAG_REPLACE_EXISTING` is not specified by application B, then application B will not replace application A as the owner.

<code>DBUS_NAME_FLAG_REPLACE_EXISTING</code>	0x2	
--	-----	--

If this flag is not set the application will only become the owner of the name if there is no current owner. If this flag is set, the application will replace the current owner if the current owner specified

DBUS_NAME_FLAG_ALLOW_REPLACEMENT.

</td></tr><tr><td>DBUS_NAME_FLAG_DO_NOT_QUEUE</td><td>0x4</td><td>

Without this flag, if an application requests a name that is already owned, the application will be placed in a queue to own the name when the current owner gives it up. If this flag is given, the application will not be placed in the queue, the request for the name will simply fail. This flag also affects behavior when an application is replaced as name owner; by default the application moves back into the waiting queue, unless this flag was provided when the application became the name owner.

</td></tr></tbody></table></div><p>

The return code can be one of the following values:

Conventional Name	Value	Description
DBUS_REQUEST_NAME_REPLY_PRIMARY_OWNER	1	The caller is now the primary owner of the name, replacing any previous owner. Either the name had no owner before, or the caller specified DBUS_NAME_FLAG_REPLACE_EXISTING and the current owner specified
DBUS_NAME_FLAG_ALLOW_REPLACEMENT.		
DBUS_REQUEST_NAME_REPLY_IN_QUEUE	2	The name already had an owner, DBUS_NAME_FLAG_DO_NOT_QUEUE was not specified, and either the current owner did not specify

DBUS_NAME_FLAG_ALLOW_REPLACEMENT or the requesting application did not specify DBUS_NAME_FLAG_REPLACE_EXISTING.

</td></tr><tr><td>DBUS_REQUEST_NAME_REPLY_EXISTS</td><td>3</td><td>The name already has an owner,

DBUS_NAME_FLAG_DO_NOT_QUEUE was specified, and either DBUS_NAME_FLAG_ALLOW_REPLACEMENT was not specified by the current owner, or DBUS_NAME_FLAG_REPLACE_EXISTING was not specified by the requesting

application.</td></tr><tr><td>DBUS_REQUEST_NAME_REPLY_ALREADY_OWNER</td><td>4</td><td>The application trying to request ownership of a name is already the owner of it.</td></tr></tbody></table></div><p>

</p></div><div class="sect3" title="org.freedesktop.DBus.ReleaseName"><div class="titlepage"><div><div><h4 class="title"><code class="literal">org.freedesktop.DBus.ReleaseName</code></h4></div></div></div><p>

As a method:
</p><pre class="programlisting">UINT32 ReleaseName (in STRING name)
</pre><p>

Message arguments:
</p><div class="informaltable"><table border="1"><colgroup><col><col><col></colgroup><thead><tr><th>Argument</th><th>Type</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>STRING</td><td>Name to release</td></tr></tbody></table></div><p>

Reply arguments:
</p><div class="informaltable"><table border="1"><colgroup><col><col><col></colgroup><thead><tr><th>Argument</th><th>Type</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>UINT32</td><td>Return value</td></tr></tbody></table></div><p>

</p><p>This method call should be sent to <code class="literal">org.freedesktop.DBus</code> and asks the message bus to release the method caller's claim to the given name. If the caller is the primary owner, a new primary owner will be selected from the queue if any other owners are waiting. If the caller is waiting in the queue for the name, the caller will removed from the queue and will not be made an owner of the name if it later becomes available. If there are no other owners in the queue for the name, it will be removed from the bus entirely.

The return code can be one of the following values:

```
</p><div class="informaltable"><table border="1"><colgroup><col><col><col></colgroup><thead><tr><th>Conventional Name</th><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>DBUS_RELEASE_NAME_REPLY_RELEASED</td><td>1</td><td>The caller has released his claim on the given name. Either the caller was the primary owner of the name, and the name is now unused or taken by somebody waiting in the queue for the name, or the caller was in the queue for the name and has now been removed from the
```

```
queue.</td></tr><tr><td>DBUS_RELEASE_NAME_REPLY_NON_EXISTENT</td><td>2</td><td>The given name does not exist on this bus.</td></tr><tr><td>DBUS_RELEASE_NAME_REPLY_NOT_OWNER</td><td>3</td><td>The caller was not the primary owner of this name, and was also not waiting in the queue to own this name.</td></tr></tbody></table></div><p>
```

```
</p></div><div class="sect3" title="org.freedesktop.DBus.ListQueuedOwners"><div class="titlepage"><div><div><h4 class="title"><a name="bus-messages-list-queued-owners"></a><code class="literal">org.freedesktop.DBus.ListQueuedOwners</code></h4></div></div></div><p>
```

As a method:

```
</p><pre class="programlisting">
```

```
    ARRAY of STRING ListQueuedOwners (in STRING name)
```

```
</pre><p>
```

Message arguments:

```
</p><div class="informaltable"><table border="1"><colgroup><col><col><col></colgroup><thead><tr><th>Argument</th><th>Type</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>STRING</td><td>The well-known bus name to query, such as <code class="literal">com.example.cappuccino</code></td></tr></tbody></table></div><p>

```

```
</p><p>
```

This method call should be sent to

```
<code class="literal">org.freedesktop.DBus</code> and lists the connections
```

currently queued for a bus name (see [#term-queued-owner](#) `title="Queued Name Owner">Queued Name Owner).`

`</p></div></div><div class="sect2" title="Message Bus Message Routing"><div class="titlepage"><div><div><h3 class="title">#message-bus-routingMessage Bus Message Routing</h3></div></div></div><p>`

Messages may have a `DESTINATION` field (see [#message-protocol-header-fields](#) `title="Header Fields">the section called Header Fields, resulting in a`

`<em class="firstterm">unicast message. If the DESTINATION field is present, it specifies a message recipient by name. Method calls and replies normally specify this field.`

The message bus must send messages (of any type) with the `DESTINATION` field set to the specified recipient,

regardless of whether the recipient has set up a match rule matching the message.

`</p><p>`

When the message bus receives a signal, if the `DESTINATION` field is absent, it is considered to

be a `broadcast signal`, and is sent to all

applications with `message matching rules` that

match the message. Most signal messages are broadcasts.

`</p><p>`

Unicast signal messages (those with a `DESTINATION`

field) are not commonly used, but they are treated like any unicast

message: they are delivered to the specified recipient, regardless of its match rules. One use for unicast signals is to

avoid a race condition in which a signal is emitted before the intended

recipient can call [#bus-messages-add-match](#) `title="org.freedesktop.DBus.AddMatch">the section called org.freedesktop.DBus.AddMatch`

to receive that signal: if the signal is sent directly to that recipient

using a unicast message, it does not need to add a match rule at all,

and there is no race condition. Another use for unicast signals,

on message buses whose security policy prevents eavesdropping,
is to

send sensitive information which should only be visible to one
recipient.

</p><p>

When the message bus receives a method call, if the
<code class="literal">DESTINATION</code> field is absent, the
call is taken to be

a standard one-to-one message and interpreted by the message
bus

itself. For example, sending an
<code class="literal">org.freedesktop.DBus.Peer.Ping</code>
message with no

<code class="literal">DESTINATION</code> will cause the
message bus itself to

reply to the ping immediately; the message bus will not make
this

message visible to other applications.

</p><p>

Continuing the <code
class="literal">org.freedesktop.DBus.Peer.Ping</code> example, if
the ping message were sent with a <code

class="literal">DESTINATION</code> name of

<code class="literal">com.yoyodyne.Screensaver</code>, then
the ping would be

forwarded, and the Yoyodyne Corporation screensaver
application would be

expected to reply to the ping.

</p><p>

Message bus implementations may impose a security policy which
prevents certain messages from being sent or received.

When a message cannot be sent or received due to a security
policy, the message bus should send an error reply, unless the
original message had the <code class="literal">NO_REPLY</code>

flag.

</p><div class="sect3" title="Eavesdropping"><div

class="titlepage"><div><div><h4 class="title"><a name="message-bus-
routing-eavesdropping">Eavesdropping</h4></div></div></div><p>

Receiving a unicast message whose <code
class="literal">DESTINATION</code>

indicates a different recipient is called

<em class="firstterm">eavesdropping. On a message bus
which acts as

a security boundary (like the standard system bus), the
security

policy should usually prevent eavesdropping, since unicast
messages

are normally kept private and may contain security-sensitive
information.

</p><p>

Eavesdropping is mainly useful for debugging tools, such as

the `dbus-monitor` tool in the reference

implementation of D-Bus. Tools which eavesdrop on the message bus

should be careful to avoid sending a reply or error in response to

messages intended for a different client.

</p><p>

Clients may attempt to eavesdrop by adding match rules (see [the section called "Match Rules"](#)) containing

the `eavesdrop='true'` match. If the message bus'

security policy does not allow eavesdropping, the match rule can

still be added, but will not have any practical effect. For compatibility with older message bus implementations, if

adding such

a match rule results in an error reply, the client may fall back to

adding the same rule with the `eavesdrop` match omitted.

</p></div><div class="sect3" title="Match Rules"><div class="titlepage"><div><div><h4 class="title">Match Rules</h4></div></div></div><p>

An important part of the message bus routing protocol is match rules. Match rules describe the messages that should be sent to a

client, based on the contents of the message. Broadcast signals

are only sent to clients which have a suitable match rule: this

avoids waking up client processes to deal with signals that are

not relevant to that client.

</p><p>

Messages that list a client as their `DESTINATION`

do not need to match the client's match rules, and are sent to that

client regardless. As a result, match rules are mainly used to

receive a subset of broadcast signals.

</p><p>

Match rules can also be used for eavesdropping (see [the section called "Eavesdropping"](#)),

if the security policy of the message bus allows it.

</p><p>

Match rules are added using the `AddMatch` bus method (see [org.freedesktop.DBus.AddMatch](#) the section called `org.freedesktop.DBus.AddMatch`).

Rules are

specified as a string of comma separated key/value pairs. Excluding a key from the rule indicates a wildcard match. For instance excluding the the member from a match rule but adding a sender would let all messages from that sender

through.

An example of a complete rule would be

```
"type='signal',sender='org.freedesktop.DBus',interface='org.freedesktop.DBus',member='Foo',path='/bar/foo',destination=':452345.34',arg2='bar'"
```

The following table describes the keys that can be used to create

a match rule:

The following table summarizes the D-Bus types.

Key	Possible Values	Description
<code>type</code>	'signal', 'method_call', 'method_return', 'error'	Match on the message type. An example of a type match is <code>type='signal'</code>
<code>sender</code>	A bus or unique name (see Bus Name and Unique Connection Name respectively)	Match messages sent by a particular sender.

An example of a sender match

is

```
sender='org.freedesktop.Hal'</td></tr><tr><td><code class="literal">interface</code></td><td>An interface name (see <a class="xref" href="#message-protocol-names-interface" title="Interface names">the section called &#8220;Interface names&#8221;</a></td><td>Match messages sent over or to a particular interface. An example of an
```

interface match is

```
interface='org.freedesktop.Hal.Manager'.
```

If a message omits the interface header, it must not match any rule

that specifies this key.</td></tr><tr><td><code class="literal">member</code></td><td>Any valid method or signal name</td><td>Matches messages which have the give method or signal name. An example of

a member match is

```
member='NameOwnerChanged'</td></tr><tr><td><code class="literal">path</code></td><td>An object path (see <a
```

[Valid Object Paths](# "Valid Object Paths")

Matches messages which are sent from or to the given object. An example of a path match is

```

path='/org/freedesktop/Hal/Manager'

```

An object path

```

class="literal">path_namespace</code>

```

Matches messages which are sent from or to an object for which the object path is either the given value, or that value followed by one or more path components.

```

</p>

<p>
  For example,
  <code>
class="literal">path_namespace='/com/example/foo'</code>
  would match signals sent by
  <code class="literal">/com/example/foo</code>
  or by
  <code
class="literal">/com/example/foo/bar</code>,
  but not by
  <code
class="literal">/com/example/foobar</code>.
</p>

<p>
  Using both <code class="literal">path</code> and
  <code class="literal">path_namespace</code> in
the same match
  rule is not allowed.
</p>

<p>
  <span class="emphasis"><em>
    This match key was added in version 0.16 of
the
    D-Bus specification and implemented by the bus
    daemon in dbus 1.5.0 and later.
  </em></span>
</p>
</td></tr><tr><td><code
class="literal">destination</code></td><td>A unique name (see <a
class="xref" href="#" title="Unique Connection Name">Unique Connection Name</a></td><td>Matches messages which are
being sent to the given unique name. An
  example of a destination match is
  <code class="literal">arg[0, 1, 2,
3, ...]</code></td><td>Any string</td><td>Arg matches are special and
are used for further restricting the

```

match based on the arguments in the body of a message. Only arguments of type `STRING` can be matched in this way. An example of an argument match would be `arg3='Foo'`. Only argument indexes from 0 to 63 should be accepted.

Argument path matches provide a specialised form of wildcard matching for path-like namespaces. They can match arguments whose type is either `STRING` or `OBJECT_PATH`. As with normal argument matches, if the argument is exactly equal to the string given in the match rule then the rule is satisfied. Additionally, there is also a match when either the string given in the match rule or the appropriate message argument ends with `'/'` and is a prefix of the other. An example argument path match is `arg0path='/aa/bb/'`. This would match messages with first arguments of `'/'`, `'/aa/'`, `'/aa/bb/'`, `'/aa/bb/cc/'` and `'/aa/bb/cc'`. It would not match messages with first arguments of `'/aa/b'`, `'/aa'` or even `'/aa/bb'`.

This is intended for monitoring directories in file system-like hierarchies, as used in the `dconf` configuration system. An application interested in all nodes in a particular hierarchy would monitor `arg0path='/ca/example/foo/'`. Then the service could emit a signal with zeroth argument `"/ca/example/foo/bar"` to represent a modification to the `bar` property, or a signal with zeroth argument `"/ca/example/"` to represent atomic modification of many properties within that directory, and the interested application would be notified in both cases.

``

the

later,

dbus 1.5.0

This match key was added in version 0.12 of D-Bus specification, implemented for STRING arguments by the bus daemon in dbus 1.2.0 and implemented for OBJECT_PATH arguments in and later.

Like a bus name, except that the string is not required to contain a '.' (period)

Match messages whose first argument is of type STRING, and is a bus name or interface name within the specified namespace. This is primarily intended for watching name owner changes for a group of related bus names, rather than for a single name or all name changes.

Because every valid interface name is also a bus name, this can also be used for messages whose first argument is an interface name.

For example, the match rule

```
member='NameOwnerChanged',arg0namespace='com.example.backend'
```

matches name owner changes for bus names such as

```
com.example.backend.foo,
```

```
com.example.backend.foo.bar,
```

and

```
com.example.backend
```

itself.

See also [the section called org.freedesktop.DBus.NameOwnerChanged](#)

This match key was added in version 0.16 of the D-Bus specification and implemented by the bus daemon in dbus 1.5.0 and later.

`</p>`
`</td></tr><tr><td><code`
`class="literal">eavesdrop</code></td><td><code`
`class="literal">'true'</code>, <code`
`class="literal">'false'</code></td><td>Since D-Bus 1.5.6, match rules`
do not
`class="literal">DESTINATION</code>`
match messages which have a `<code`
`class="literal">DESTINATION</code>`
field unless the match rule specifically
requests this
(see [the section called](#message-bus-routing-eavesdropping)
[Eavesdropping](#message-bus-routing-eavesdropping)
by specifying `<code`
`class="literal">eavesdrop='true'</code>`
in the match rule. `<code`
`class="literal">eavesdrop='false'</code>`
restores the default behaviour. Messages are
delivered to their `<code`
`class="literal">DESTINATION</code>`
regardless of match rules, so this match does not
affect normal delivery of unicast messages.
If the message bus has a security policy which
forbids
eavesdropping, this match may still be used
without error,
but will not have any practical effect.
In older versions of D-Bus, this match was not
allowed
in match rules, and all match rules behaved as if
`<code class="literal">eavesdrop='true'</code>` had
been used.

`</td></tr></tbody></table></div><p>`
`</p></div></div><div class="sect2" title="Message Bus Starting`
`Services"><div class="titlepage"><div><div><h3 class="title"><a`
`name="message-bus-starting-services">Message Bus Starting`
`Services</h3></div></div></div><p>`

The message bus can start applications on behalf of other applications.

In CORBA terms, this would be called `<em`
`class="firstterm">activation`.

An application that can be started in this way is called a
`<em class="firstterm">service`.

`</p><p>`

With D-Bus, starting a service is normally done by name. That
is,

applications ask the message bus to start some program that
will own a

well-known name, such as `<code`
`class="literal">org.freedesktop.TextEditor</code>`.

This implies a contract documented along with the name

`org.freedesktop.TextEditor` for which objects the owner of that name will provide, and what interfaces those objects will have.

To find an executable corresponding to a particular name, the bus daemon

looks for `service description files`. Service description files define a mapping from names to executables. Different

kinds of message bus will look for these files in different places, see

[Well-known Message Bus Instances](#) the section called `Well-known Message Bus Instances`.

Service description files have the `.service` file extension. The message bus will only load service description files

ending with `.service`; all other files will be ignored. The file format

is similar to that of [desktop entries](#). All service description files must be in UTF-8 encoding. To ensure that there will be no name collisions, service files

must be namespaced using the same mechanism as messages and service names.

[FIXME the file format should be much better specified than "similar to `.desktop entries`" esp. since desktop entries are already badly-specified. ;-)]

These sections from the specification apply to service files as well:

```
</p><div class="itemizedlist"><ul class="itemizedlist" type="disc"><li class="listitem"><p>General syntax</p></li><li class="listitem"><p>Comment format</p></li></ul></div><p>
```

```
</p><div class="figure"><a name="idp5671872"></a><p class="title"><b>Figure 9. Example service description file</b></p><div class="figure-contents"><pre class="programlisting"># Sample service description file
[D-BUS Service]
```

```
Names=org.freedesktop.ConfigurationDatabase;org.gnome.GConf;
Exec=/usr/libexec/gconfd-2
```

```
</pre></div></div><p><br class="figure-break">
```

When an application asks to start a service by name, the bus daemon tries to find a service that will own that name. It then tries to spawn the executable associated with it. If this fails, it will report an error. [FIXME what happens if two .service files offer the same service; what kind of error is reported, should we have a way for the client to choose one?]

The executable launched will have the environment variable `DBUS_STARTER_ADDRESS` set to the address of the message bus so it can connect and request the appropriate names.

The executable being launched may want to know whether the message bus starting it is one of the well-known message buses (see [the section called "Well-known Message Bus Instances"](#)). To facilitate this, the bus must also set the `DBUS_STARTER_BUS_TYPE` environment variable if it is one of the well-known buses. The currently-defined values for this variable are `system` for the systemwide message bus, and `session` for the per-login-session message bus. The new executable must still connect to the address given in `DBUS_STARTER_ADDRESS`, but may assume that the resulting connection is to the well-known bus.

[FIXME there should be a timeout somewhere, either specified in the .service file, by the client, or just a global value and if the client being activated fails to connect within that timeout, an error should be sent back.]

[Message Bus Service Scope](#)

The "scope" of a service is its "per-", such as per-session, per-machine, per-home-directory, or per-display. The reference implementation doesn't yet support starting services in a different

scope from the message bus itself. So e.g. if you start a service on the session bus its scope is per-session.

We could add an optional scope to a bus name. For example, for per-(display,session pair), we could have a unique ID for each display generated automatically at login and set on screen 0 by executing a special "set display ID" binary. The ID would be stored in a `_DBUS_DISPLAY_ID` property and would be a string of random bytes. This ID would then be used to scope names. Starting/locating a service could be done by ID-name pair rather than only by name.

Contrast this with a per-display scope. To achieve that, we would want a single bus spanning all sessions using a given display. So we might set a `_DBUS_DISPLAY_BUS_ADDRESS` property on screen 0 of the display, pointing to this bus.

Well-known Message Bus Instances

Well-known Message Bus Instances

Two standard message bus instances are defined here, along with how to locate them and where their service files live.

Login session message bus

Each time a user logs in, a `login session message bus` may be started. All applications in the user's login session may interact with one another using this message bus.

The address of the login session message bus is given in the `DBUS_SESSION_BUS_ADDRESS` environment variable. If that variable is not set, applications may also try to read the address from the X Window System root window property `_DBUS_SESSION_BUS_ADDRESS`. The root window property must have type `STRING`. The environment variable should have precedence over the

root window property.

The address of the login session message bus is given in the environment variable. If `DBUS_SESSION_BUS_ADDRESS` is not set, or if it's set to the string "autolaunch:", the system should use platform-specific methods of locating a running D-Bus session server, or starting one if a running instance cannot be found. Note that this mechanism is not recommended for attempting to determine if a daemon is running. It is inherently racy to attempt to make this determination, since the bus daemon may be started just before or just after the determination is made.

Therefore, it is recommended that applications do not try to make this determination for their functionality purposes, and instead they should attempt to start the server.

`<div class="sect4" title="X Windowing System"><div class="titlepage"><div><div><h5 class="title">X Windowing System</h5></div></div></div><p>`

For the X Windowing System, the application must locate the window owner of the selection represented by the atom formed by concatenating:

`</p><div class="itemizedlist"><ul class="itemizedlist" type="disc"><li class="listitem"><p>the literal string "_DBUS_SESSION_BUS_SELECTION_"</p><li class="listitem"><p>the current user's username</p><li class="listitem"><p>the literal character '_' (underscore)</p><li class="listitem"><p>the machine's ID</p></div><p>`

The following properties are defined for the window that owns this X selection:

`</p><div class="informaltable"><table border="1"><colgroup><col><col></colgroup><tbody><tr><td><p>Atom</p></td><td><p>meaning</p></td></tr><tr><td><p>_DBUS_SESSION_BUS_ADDRESS</p></td><td><p>the actual address of the server socket</p></td></tr><tr><td>`

```

        <p>_DBUS_SESSION_BUS_PID</p>
    </td><td>
        <p>the PID of the server process</p>
    </td></tr></tbody></table></div><p>
</p><p>
    At least the _DBUS_SESSION_BUS_ADDRESS property MUST be
    present in this window.
</p><p>
    If the X selection cannot be located or if reading the
    properties from the window fails, the implementation MUST
conclude
    that there is no D-Bus server running and proceed to start
a new
    server. (See below on concurrency issues)
</p><p>
    Failure to connect to the D-Bus server address thus
obtained
    MUST be treated as a fatal connection error and should be
reported
    to the application.
</p><p>
    As an alternative, an implementation MAY find the
information
    in the following file located in the current user's home
directory,
    in subdirectory .dbus/session-bus/:
    <p><div class="itemizedlist"><ul class="itemizedlist"
type="disc"><li class="listitem"><p>the machine's ID</p></li><li
class="listitem"><p>the literal character '-' (dash)</p></li><li
class="listitem"><p>the X display without the screen number, with the
    following prefixes removed, if present: ":",
"localhost:"
    ."localhost.localdomain:". That is, a display of
"localhost:10.0" produces just the number
"10"</p></li></ul></div><p>
</p><p>
    The contents of this file NAME=value assignment pairs and
allowed
    lines starting with # are comments (no comments are
    otherwise). The following variable names are defined:
    <p><div class="informaltable"><table
border="1"><colgroup><col><col></colgroup><tbody><tr><td>
        <p>Variable</p>
    </td><td>
        <p>meaning</p>
    </td></tr><tr><td>
        <p>DBUS_SESSION_BUS_ADDRESS</p>
    </td><td>
        <p>the actual address of the server socket</p>
    </td></tr><tr><td>
        <p>DBUS_SESSION_BUS_PID</p>
    </td><td>

```

```
        <p>the PID of the server process</p>
    </td></tr><tr><td>
        <p>DBUS_SESSION_BUS_WINDOWID</p>
    </td><td>
        <p>the window ID</p>
    </td></tr></tbody></table></div><p>
```

```
</p><p>
    At least the DBUS_SESSION_BUS_ADDRESS variable MUST be
present
    in this file.
</p><p>
    Failure to open this file MUST be interpreted as absence
of a
    running server. Therefore, the implementation MUST proceed
to
    attempting to launch a new bus server if the file cannot
be
    opened.
</p><p>
    However, success in opening this file MUST NOT lead to the
connect to
    conclusion that the server is running. Thus, a failure to
NOT be
    the bus address obtained by the alternative method MUST
established,
    considered a fatal error. If the connection cannot be
settings or
    the implementation MUST proceed to check the X selection
to start the server on its own.
</p><p>
    If the implementation concludes that the D-Bus server is
not
    running it MUST attempt to start a new server and it MUST
also
    ensure that the daemon started as an effect of the
"autolaunch"
    mechanism provides the lookup mechanisms described above,
so
    subsequent calls can locate the newly started server. The
concurrent
    implementation MUST also ensure that if two or more
all other
    initiations happen, only one server remains running and
and
    initiations are able to obtain the address of this server
ensure that
    connect to it. In other words, the implementation MUST
without
    the X selection is not present when it attempts to set it,
    allowing another process to set the selection between the
    verification and the setting (e.g., by using XGrabServer /
    XungrabServer).
```

</h5></div></div></div><p> On Unix systems, the session bus should search for .service files in `<code class="literal">$XDG_DATA_DIRS/dbus-1/services</code>` as defined by the [>XDG Base Directory Specification. Implementations may also search additional locations, which should be searched with lower priority than anything in XDG_DATA_HOME, XDG_DATA_DIRS or their respective defaults; for example, the reference implementation also looks in `<code class="literal">\${datadir}/dbus-1/services</code>` as set at compile time.](http://standards.freedesktop.org/basedir-spec/basedir-spec-latest.html)

</p><p>As described in the XDG Base Directory Specification, software packages should install their session .service files to their configured `<code class="literal">${datadir}/dbus-1/services</code>`, where `<code class="literal">${datadir}</code>` is as defined by the GNU coding standards. System administrators or users can arrange for these service files to be read by setting XDG_DATA_DIRS or by symlinking them into the default locations.

System message bus</h4></div></div></div><p>A computer may have a *system message bus*, accessible to all applications on the system. This message bus may be used to broadcast system events, such as adding new hardware devices, changes in the printer queue, and so forth. The address of the system message bus is given in the `<code class="literal">DBUS_SYSTEM_BUS_ADDRESS</code>` environment variable. If that variable is not set, applications should try to connect to the well-known address

```

        <code
class="literal">unix:path=/var/run/dbus/system_bus_socket</code>.
        <sup>[<a name="idp5733888" href="#ftn.idp5733888"
class="footnote">2</a>]</sup>
        </p><p>
            On Unix systems, the system bus should default to searching
            for .service files in
            <code class="literal">/usr/local/share/dbus-1/system-
services</code>,
            <code class="literal">/usr/share/dbus-1/system-
services</code> and
            <code class="literal">/lib/dbus-1/system-services</code>,
with that order
            of precedence. It may also search other implementation-
specific
            locations, but should not vary these locations based on
environment
            variables.
            <sup>[<a name="idp5738096" href="#ftn.idp5738096"
class="footnote">3</a>]</sup>
        </p><p>
            Software packages should install their system .service
            files to their configured
            <code class="literal">${datadir}/dbus-1/system-
services</code>,
            where <code class="literal">${datadir}</code> is as defined
by the GNU
            coding standards. System administrators can arrange
            for these service files to be read by editing the system
bus'
            configuration file or by symlinking them into the default
            locations.
        </p></div></div><div class="sect2" title="Message Bus
Messages"><div class="titlepage"><div><div><h3 class="title"><a
name="message-bus-messages"></a>Message Bus
Messages</h3></div></div></div><p>
            The special message bus name <code
class="literal">org.freedesktop.DBus</code>
            responds to a number of additional messages.
        </p><div class="sect3" title="org.freedesktop.DBus.Hello"><div
class="titlepage"><div><div><h4 class="title"><a name="bus-messages-
hello"></a><code
class="literal">org.freedesktop.DBus.Hello</code></h4></div></div></di
v><p>
            As a method:
        </p><pre class="programlisting">
            STRING Hello ()
        </pre><p>
            Reply arguments:
        </p><div class="informaltable"><table
border="1"><colgroup><col><col><col></colgroup><thead><tr><th>Argument
</th><th>Type</th><th>Description</th></tr></thead><tbody><tr><td>0</t

```

d><td>STRING</td><td>Unique name assigned to the connection</td></tr></tbody></table></div><p>

</p><p>

Before an application is able to send messages to other applications

it must send the `org.freedesktop.DBus.Hello` message to the message bus to obtain a unique name. If an application without

a unique name tries to send a message to another application, or a message to the message bus itself that isn't the `org.freedesktop.DBus.Hello` message, it will be disconnected from the bus.

</p><p>

There is no corresponding "disconnect" request; if a client wishes to

disconnect from the bus, it simply closes the socket (or other

communication channel).

</p></div><div class="sect3" title="org.freedesktop.DBus.ListNames"><div class="titlepage"><div><div><h4 class="title"><code class="literal">org.freedesktop.DBus.ListNames</code></h4></div></div></div><p>

</p><div class="informaltable"><table border="1"><colgroup><col><col><col></colgroup><thead><tr><th>Argument</th><th>Type</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>STRING</td><td>Match rule to remove from the connection</td></tr></tbody></table></div><p>

Removes the first rule that matches (see the section called “Match Rules”).

If the rule is not found the <code class="literal">org.freedesktop.DBus.Error.MatchRuleNotFound</code> error is returned.

</p></div><div class="sect3" title="org.freedesktop.DBus.GetId"><div class="titlepage"><div><div><h4 class="title"><code class="literal">org.freedesktop.DBus.GetId</code></h4></div></div></div><p>

As a method:

</p><pre class="programlisting">

GetId (out STRING id)

</pre><p>

Reply arguments:

</p><div class="informaltable"><table border="1"><colgroup><col><col><col></colgroup><thead><tr><th>Argument</th><th>Type</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>STRING</td><td>Unique ID identifying the bus daemon</td></tr></tbody></table></div><p>

Gets the unique ID of the bus. The unique ID here is shared among all addresses the

bus daemon is listening on (TCP, UNIX domain socket, etc.) and its format is described in

[the section called “UUIDs”](#uuids "UUIDs"). Each address the bus is listening on also has its own unique

ID, as described in [the section called “Server Addresses”](#addresses "Server Addresses"). The per-bus and per-address IDs are not related.

There is also a per-machine ID, described in [the section called “`org.freedesktop.DBus.Peer`”](#standard-interfaces-peer "org.freedesktop.DBus.Peer") and returned

by `org.freedesktop.DBus.Peer.GetMachineId()`.

For a desktop session bus, the bus ID can be used as a way to uniquely identify a user's session.

[Glossary](#)

[Glossary](#)

This glossary defines some of the terms used in this specification.

Bus Name

The message bus maintains an association between names and connections. (Normally, there's one connection per application.) A

bus name is simply an identifier used to locate connections.

For

example, the hypothetical `com.yoyodyne.Screensaver` name might be used to send a message to a screensaver from Yoyodyne

Corporation. An application is said to *own* a

name if the message bus has associated the application's connection

with the name. Names may also have *queued*

owners (see [Queued Name Owner](#term-queued-owner "Queued Name Owner")).

The bus assigns a unique name to each connection, see [Unique Connection Name](#term-unique-name "Unique Connection Name"). Other names can be thought of as "well-known names" and are used to find applications that offer specific functionality.

See [the section called “Bus names”](#message-protocol-names-bus "Bus names") for details of

the syntax and naming conventions for bus names.

Message

A message is the atomic unit of communication via the D-Bus protocol. It consists of a *header*

and a

`<em class="firstterm">body`; the body is made up of `<em class="firstterm">arguments`.

`</p></dd><dt>Message Bus</dt><dd><p>`

The message bus is a special application that forwards or routes messages between a group of applications connected to the message bus. It also manages `<em class="firstterm">names` used for routing messages.

`</p></dd><dt>Name</dt><dd><p>`

See `Bus Name`. "Name" may also be used to refer to some of the other names in D-Bus, such as interface names.

`</p></dd><dt>Namespace</dt><dd><p>`

Used to prevent collisions when defining new interfaces, bus names etc. The convention used is the same one Java uses for defining classes: a reversed domain name. See `the section called “Bus names”`, `the section called “Interface names”`, `the section called “Error names”`, `the section called “Valid Object Paths”`.

`</p></dd><dt>Object</dt><dd><p>`

Each application contains `<em class="firstterm">objects`, which have `<em class="firstterm">interfaces` and `<em class="firstterm">methods`. Objects are referred to by a name, called a `<em class="firstterm">path`.

`</p></dd><dt>One-to-One</dt><dd><p>`

An application talking directly to another application, without going through a message bus. One-to-one connections may be "peer to peer" or "client vs. server." The D-Bus protocol has no concept of messages is symmetrical (full duplex).

`</p></dd><dt>Path</dt><dd><p>`

Object references (object names) in D-Bus are organized into a filesystem-style hierarchy, so each object is named by a path. As in

LDAP, there's no difference between "files" and "directories"; a path can refer to an object, while still having child objects below it.

[Queued Name Owner](#)

Each bus name has a primary owner; messages sent to the name go to the primary owner. However, certain names also maintain a queue of

secondary owners "waiting in the wings." If the primary owner releases the name, then the first secondary owner in the queue automatically becomes the new owner of the name.

[Service](#)

A service is an executable that can be launched by the bus daemon.

Services normally guarantee some particular features, for example they

may guarantee that they will request a specific name such as "org.freedesktop.Screensaver", have a singleton object "/org/freedesktop/Application", and that object will implement the

interface "org.freedesktop.ScreensaverControl".

[Service Description Files](#)

".service files" tell the bus about service applications that can be

launched (see [Service](#)). Most importantly they

provide a mapping from bus names to services that will request those

names when they start up.

[Unique Connection Name](#)

The special name automatically assigned to each connection by the

message bus. This name will never change owner, and will be unique

(never reused during the lifetime of the message bus).

It will begin with a ':' character.

¹ Lockfiles are used instead of real file

locking `fcntl()` because

implementations are still flaky on network filesystems.

² `fcntl()`

The D-Bus reference implementation actually honors the `$(localstatedir)` configure option for this address, on both client and server side.

^{[[3](#)]} The system bus is security-sensitive and is typically executed by an init system with a clean environment. Its launch helper process is particularly security-sensitive, and specifically clears its own environment.

<sect1 id="introduction">
  <title>Introduction</title>
  <para>
    D-Bus is a system for low-latency, low-overhead, easy to use
    interprocess communication (IPC). In more detail:
    <itemizedlist>
      <listitem>
        <para>
          D-Bus is <emphasis>low-latency</emphasis> because it is
          designed
          to avoid round trips and allow asynchronous operation,
          much like
          the X protocol.
        </para>
      </listitem>
      <listitem>
        <para>
          D-Bus is <emphasis>low-overhead</emphasis> because it uses

```

binary protocol, and does not have to convert to and from a text format such as XML. Because D-Bus is intended for potentially high-resolution same-machine IPC, not primarily for Internet IPC, this is an interesting optimization.

</para>
</listitem>
<listitem>
<para>
D-Bus is <emphasis>easy to use</emphasis> because it works in terms of <firstterm>messages</firstterm> rather than byte streams, and automatically handles a lot of the hard IPC issues. Also, the D-Bus library is designed to be wrapped in a way that lets developers use their framework's existing object/type system, rather than learning a new one specifically for IPC.

</para>
</listitem>
</itemizedlist>
</para>

<para>
The base D-Bus protocol is a one-to-one (peer-to-peer or client-server) protocol, specified in <xref linkend="message-protocol"/>. That is, it is a system for one application to talk to a single other application. However, the primary intended application of the protocol is the D-Bus <firstterm>message bus</firstterm>, specified in <xref linkend="message-bus"/>. The message bus is a special application that accepts connections from multiple other applications, and forwards messages among them.

</para>

<para>
Uses of D-Bus include notification of system changes (notification of when a camera is plugged in to a computer, or a new version of some software has been installed), or desktop interoperability, for example a file monitoring service or a configuration service.

</para>

```
<para>
  D-Bus is designed for two specific use cases:
  <itemizedlist>
    <listitem>
      <para>
        A "system bus" for notifications from the system to user
sessions,
        and to allow the system to request input from user
sessions.
      </para>
    </listitem>
    <listitem>
      <para>
        A "session bus" used to implement desktop environments
such as
        GNOME and KDE.
      </para>
    </listitem>
  </itemizedlist>
  D-Bus is not intended to be a generic IPC system for any
possible
  application, and intentionally omits many features found in
other
  IPC systems for this reason.
</para>

<para>
  At the same time, the bus daemons offer a number of features not
found in
  other IPC systems, such as single-owner "bus names" (similar to
X
  selections), on-demand startup of services, and security
policies.
  In many ways, these features are the primary motivation for
developing
  D-Bus; other systems would have sufficed if IPC were the only
goal.
</para>

<para>
  D-Bus may turn out to be useful in unanticipated applications,
but future
  versions of this spec and the reference implementation probably
will not
  incorporate features that interfere with the core use cases.
</para>

<para>
  The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL
NOT",
```

"SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119. However, the document could use a serious audit to be sure it makes sense to do so. Also, they are not capitalized.

```
<sect2 id="stability">
  <title>Protocol and Specification Stability</title>
  <para>
    The D-Bus protocol is frozen (only compatible extensions are
    allowed) as of November 8, 2006. However, this specification could still
    use a fair bit of work to make interoperable reimplementations possible
    without reference to the D-Bus reference implementation. Thus, this
    specification is not marked 1.0. To mark it 1.0, we'd like to see
    someone invest significant effort in clarifying the specification
    language, and growing the specification to cover more aspects
    of the reference implementation's behavior.
  </para>
  <para>
    Until this work is complete, any attempt to reimplement D-Bus
    will probably require looking at the reference implementation
    and/or asking questions on the D-Bus mailing list about intended behavior.
    Questions on the list are very welcome.
  </para>
  <para>
    Nonetheless, this document should be a useful starting point
    and is to our knowledge accurate, though incomplete.
  </para>
</sect2>
```

```
</sect1>
```

```
<sect1 id="type-system">
  <title>Type System</title>
```

```
<para>
  D-Bus has a type system, in which values of various types can be
  serialized into a sequence of bytes referred to as the
  <firstterm>wire format</firstterm> in a standard way.
  Converting a value from some other representation into the wire
```

format is called `<firstterm>marshaling</firstterm>` and converting it back from the wire format is `<firstterm>unmarshaling</firstterm>`.

`<sect2 id="message-protocol-signatures">`
`<title>Type Signatures</title>`

`<para>`
The D-Bus protocol does not include type tags in the marshaled data; a block of marshaled values must have a known `<firstterm>type signature</firstterm>`. The type signature is made up of `<firstterm>type codes</firstterm>`. A type code is an ASCII character representing the type of a value. Because ASCII characters are used, the type signature will always form a valid ASCII string. A simple string compare determines whether two type signatures are equivalent.

`<para>`
As a simple example, the type code for 32-bit integer (`<literal>INT32</literal>`) is the ASCII character 'i'. So the signature for a block of values containing a single `<literal>INT32</literal>` would be:
`<programlisting>`
"i"
`</programlisting>`
A block of values containing two `<literal>INT32</literal>` would have this signature:
`<programlisting>`
"ii"
`</programlisting>`

`<para>`
All `<firstterm>basic</firstterm>` types work like `<literal>INT32</literal>` in this example. To marshal and unmarshal basic types, you simply read one value from the data block corresponding to each type code in the signature. In addition to basic types, there are four `<firstterm>container</firstterm>` types: `<literal>STRUCT</literal>`, `<literal>ARRAY</literal>`, `<literal>VARIANT</literal>`, and `<literal>DICT_ENTRY</literal>`.

<para>
<literal>STRUCT</literal> has a type code, ASCII character 'r', but this type code does not appear in signatures. Instead, ASCII characters '(' and ')' are used to mark the beginning and end of the struct.

So for example, a struct containing two integers would have this

signature:

```
<programlisting>
```

```
"(ii)"
```

```
</programlisting>
```

Structs can be nested, so for example a struct containing an integer and another struct:

```
<programlisting>
```

```
"(i(ii))"
```

```
</programlisting>
```

The value block storing that struct would contain three integers; the

type signature allows you to distinguish "(i(ii))" from "((ii)i)" or

"(iii)" or "iii".

</para>

<para>

The <literal>STRUCT</literal> type code 'r' is not currently used in the D-Bus protocol,

but is useful in code that implements the protocol. This type code

is specified to allow such code to interoperate in non-protocol contexts.

</para>

<para>

Empty structures are not allowed; there must be at least one type code between the parentheses.

</para>

<para>

<literal>ARRAY</literal> has ASCII character 'a' as type code. The array type code must be

followed by a <firstterm>single complete type</firstterm>. The single

complete type following the array is the type of each array element. So

the simple example is:

```
<programlisting>
```

```
"ai"
```

```
</programlisting>
```

which is an array of 32-bit integers. But an array can be of any type,

such as this array-of-struct-with-two-int32-fields:

```
<programlisting>
    "a(ii)"
</programlisting>
Or this array of array of integer:
<programlisting>
    "aai"
</programlisting>
</para>
```

<para>
The phrase <firstterm>single complete type</firstterm>
deserves some
definition. A single complete type is a basic type code, a
variant type code,
an array with its element type, or a struct with its fields.
So the following signatures are not single complete types:

```
<programlisting>
    "aa"
</programlisting>
<programlisting>
    "(ii)"
</programlisting>
<programlisting>
    "ii)"
</programlisting>
```

And the following signatures contain multiple complete types:

```
<programlisting>
    "ii"
</programlisting>
<programlisting>
    "aiai"
</programlisting>
<programlisting>
    "(ii)(ii)"
</programlisting>
```

Note however that a single complete type may
<emphasis>contain</emphasis>
multiple other single complete types.

</para>

<para>
<literal>VARIANT</literal> has ASCII character 'v' as its type
code. A marshaled value of
type <literal>VARIANT</literal> will have the signature of a
single complete type as part
of the <emphasis>value</emphasis>. This signature will be
followed by a
marshaled value of that type.

</para>

<para>

A `<literal>DICT_ENTRY</literal>` works exactly like a struct, but rather than parentheses it uses curly braces, and it has more restrictions.

The restrictions are: it occurs only as an array element type; it has exactly two single complete types inside the curly braces; the first single complete type (the "key") must be a basic type rather than a container type. Implementations must not accept dict entries outside of arrays, must not accept dict entries with zero, one, or more than two fields, and must not accept dict entries with non-basic-typed keys. A dict entry is always a key-value pair.

</para>

<para>
The first field in the `<literal>DICT_ENTRY</literal>` is always the key.

A message is considered corrupt if the same key occurs twice in the same array of `<literal>DICT_ENTRY</literal>`. However, for performance reasons implementations are not required to reject dicts with duplicate keys.

</para>

<para>
In most languages, an array of dict entry would be represented as a map, hash table, or dict object.

</para>

<para>
The following table summarizes the D-Bus types.

Conventional Name	Code	Description
<code><literal>INVALID</literal></code>		
0	(ASCII NUL)	

```

        <entry>Not a valid type code, used to terminate
signatures</entry>

</tbody>

</tgroup>

</informaltable>

</para>

</sect2>

<sect2 id="message-protocol-marshaling">
 <title>Marshaling (Wire Format)</title>

<para>
 Given a type signature, a block of bytes can be converted into typed bytes. Byte order and alignment issues are handled uniformly for all D-Bus types.</para>

<para>
 A block of bytes has an associated byte order. The byte order has to be discovered in some way; for D-Bus messages, the byte order is part of the message header as described in <xref linkend="message-protocol-messages"/>. For now, assume that the byte order is known to be either little endian or big endian.</para>

</para>

<para>

Each value in a block of bytes is aligned "naturally," for example

4-byte values are aligned to a 4-byte boundary, and 8-byte values to an

8-byte boundary. To properly align a value, <firstterm>alignment

padding</firstterm> may be necessary. The alignment padding must always

be the minimum required padding to properly align the following value;

padding must and it must always be made up of nul bytes. The alignment

padding must not be left uninitialized (it can't contain garbage), and more

padding than required must not be used.

</para>

<para>

Given all this, the types are marshaled on the wire as follows:

<informaltable>

<tgroup cols="3">

<thead>

<title>Valid Object Paths</title>
```

```
<para>
  An object path is a name used to refer to an object
instance.
  Conceptually, each participant in a D-Bus message exchange
may have
  any number of object instances (think of C++ or Java
objects) and each
  such instance will have a path. Like a filesystem, the
object
  instances in an application form a hierarchical tree.
</para>
```

```
<para>
```

The following rules define a valid object path.
Implementations must not send or accept messages with invalid object paths.

- <itemizedlist>
 - <listitem>
 - <para>

The path may be of any length.
- </listitem>
 - <listitem>
 - <para>

The path must begin with an ASCII '/' (integer 47) character, and must consist of elements separated by slash characters.
- </listitem>
 - <listitem>
 - <para>

Each element must only contain the ASCII characters "[A-Z][a-z][0-9]_"
- </listitem>
 - <listitem>
 - <para>

No element may be the empty string.
- </listitem>
 - <listitem>
 - <para>

Multiple '/' characters cannot occur in sequence.
- </listitem>
 - <listitem>
 - <para>

A trailing '/' character is not allowed unless the path is the root path (a single '/' character).

</itemizedlist>
</para>

<para>
reversed Object paths are often namespaced by starting with a domain name and containing an interface version number, in the same way as
<link linkend="message-protocol-names-interface">interface names</link> and
<link linkend="message-protocol-names-bus">well-known bus names</link>.

or This makes it possible to implement more than one service,
more than one version of a service, in the same process,
even if the services share a connection but cannot otherwise
co-operate (for instance, if they are implemented by
different plugins).
</para>

<para>

<sect1 id="message-protocol">

<title>Message Protocol</title>

<para>

A <firstterm>message</firstterm> consists of a

<firstterm>header</firstterm> and a <firstterm>body</firstterm>.

If you

think of a message as a package, the header is the address, and the body

contains the package contents. The message delivery system uses the header

information to figure out where to send the message and how to interpret

it; the recipient interprets the body of the message.

</para>

<para>

The body of the message is made up of zero or more

<firstterm>arguments</firstterm>, which are typed values, such as an

integer or a byte array.

</para>

<para>

Both header and body use the D-Bus [type-system](#) and format for serializing data.

Message Format

A message consists of a header and a body. The header is a block of values with a fixed signature and meaning. The body is a separate block of values, with a signature specified in the header.

The length of the header must be a multiple of 8, allowing the body to begin on an 8-byte boundary when storing the entire message in a single buffer. If the header does not naturally end on an 8-byte boundary up to 7 bytes of nul-initialized alignment padding must be added.

The message body need not end on an 8-byte boundary.

The maximum length of a message, including header, header alignment padding, and body is 2 to the 27th power or 134217728. Implementations must not send or accept messages exceeding this size.

The signature of the header is:

```
"yyyyuua(yv)"
```

Written out more readably, this is:

```
BYTE, BYTE, BYTE, BYTE, UINT32, UINT32, ARRAY of STRUCT of (BYTE,VARIANT)
```

These values have the following meanings:

<sect3 id="message-protocol-header-fields">
<title>Header Fields</title>

<para>
The array at the end of the header contains
<firstterm>header
fields</firstterm>, where each field is a 1-byte field code
followed
by a field value. A header must contain the required header
fields for
its message type, and zero or more of any optional header
fields. Future versions of this protocol specification may
add new
fields. Implementations must ignore fields they do not
understand. Implementations must not invent their own header
fields;
only changes to this specification may introduce new header
fields.
</para>

<para>
Again, if an implementation sees a header field code that it
does not
expect, it must ignore that field, as it will be part of a
new
(but compatible) version of this specification. This also
applies
to known header fields appearing in unexpected messages, for
example: if a signal has a reply serial it must be ignored
even though it has no meaning as of this version of the
spec.
</para>

<para>
However, implementations must not send or accept known
header fields
with the wrong type stored in the field value. So for
example a
message with an <literal>INTERFACE</literal> field of type
<literal>UINT32</literal> would be considered corrupt.
</para>

(period) character.</para></listitem>
    <listitem><para>Interface names must not exceed the maximum
name length.</para></listitem>
</itemizedlist>
</para>

<para>
    Interface names should start with the reversed DNS domain
name of
    the author of the interface (in lower-case), like interface
names
    in Java. It is conventional for the rest of the interface
name
    to consist of words run together, with initial capital
letters
    on all words ("CamelCase"). Several levels of hierarchy can
be used.
    It is also a good idea to include the major version of the
interface
    in the name, and increment it if incompatible changes are
made;
    this way, a single object can implement several versions of
an
    interface in parallel, if necessary.
</para>

<para>
    For instance, if the owner of <literal>example.com</literal>
is
    developing a D-Bus API for a music player, they might define
    interfaces called
<literal>com.example.MusicPlayer1</literal>,
    <literal>com.example.MusicPlayer1.Track</literal> and
    <literal>com.example.MusicPlayer1.Seekable</literal>.
</para>

<para>

    Like <link linkend="message-protocol-names-
interface">interface
    names</link>, well-known bus names should start with the
    reversed DNS domain name of the author of the interface (in
    lower-case), and it is conventional for the rest of the
well-known
    bus name to consist of words run together, with initial
    capital letters. As with interface names, including a
version
    number in well-known bus names is a good idea; it's possible
to
    have the well-known bus name for more than one version
    simultaneously if backwards compatibility is required.
</para>

<para>
    If a well-known bus name implies the presence of a "main"
interface,
    that "main" interface is often given the same name as
    the well-known bus name, and situated at the corresponding
object
    path. For instance, if the owner of
<literal>example.com</literal>
    is developing a D-Bus API for a music player, they might
define
    that any application that takes the well-known name
    <literal>com.example.MusicPlayer1</literal> should have an
object
    at the object path
<literal>/com/example/MusicPlayer1</literal>
    which implements the interface
    <literal>com.example.MusicPlayer1</literal>.
</para>
</sect3>
<sect3 id="message-protocol-names-member">
    <title>Member names</title>
    <para>
        Member (i.e. method or signal) names:
        <itemizedlist>
        <listitem><para>Must only contain the ASCII characters
            "[A-Z][a-z][0-9]_" and may not begin with a
            digit.</para></listitem>
    </itemizedlist>

```

`<listitem><para>Must not contain the '.' (period) character.</para></listitem>`

`<listitem><para>Must not exceed the maximum name length.</para></listitem>`

`<listitem><para>Must be at least 1 byte in length.</para></listitem>`

`</itemizedlist>`

`</para>`

`<para>`

It is conventional for member names on D-Bus to consist of capitalized words with no punctuation ("camel-case").

Method names should usually be verbs, such as

`<literal>GetItems</literal>`, and signal names should usually

be

a description of an event, such as

`<literal>ItemsChanged</literal>`.

`</para>`

`</sect3>`

`<title>Message Types</title>`

`<para>`

Each of the message types (`<literal>METHOD_CALL</literal>`, `<literal>METHOD_RETURN</literal>`, `<literal>ERROR</literal>`, and

`<literal>SIGNAL</literal>`) has its own expected usage conventions and header fields.

This section describes these conventions.

`</para>`

`<sect3 id="message-protocol-types-method">`

<title>Method Calls</title>
<para>
Some messages invoke an operation on a remote object. These
are
called method call messages and have the type tag
<literal>METHOD_CALL</literal>. Such
messages map naturally to methods on objects in a typical
program.
</para>
<para>
A method call message is required to have a
<literal>MEMBER</literal> header field
indicating the name of the method. Optionally, the message
has an
<literal>INTERFACE</literal> field giving the interface the
method is a part of. In the
absence of an <literal>INTERFACE</literal> field, if two
interfaces on the same object have
a method with the same name, it is undefined which of the
two methods
will be invoked. Implementations may also choose to return
an error in
this ambiguous case. However, if a method name is unique
implementations must not require an interface field.
</para>
<para>
Method call messages also include a <literal>PATH</literal>
field
indicating the object to invoke the method on. If the call
is passing
through a message bus, the message will also have a
<literal>DESTINATION</literal> field giving the name of the
connection
to receive the message.
</para>
<para>
When an application handles a method call message, it is
required to
return a reply. The reply is identified by a
<literal>REPLY_SERIAL</literal> header field
indicating the serial number of the
<literal>METHOD_CALL</literal> being replied to. The
reply can have one of two types; either
<literal>METHOD_RETURN</literal> or <literal>ERROR</literal>.
</para>
<para>
If the reply has type <literal>METHOD_RETURN</literal>, the
arguments to the reply message
are the return value(s) or "out parameters" of the method
call.
If the reply has type <literal>ERROR</literal>, then an
"exception" has been thrown,

and the call fails; no return value will be provided. It makes

no sense to send multiple replies to the same method call.
</para>

<para>
Even if a method call has no return values, a
<literal>METHOD_RETURN</literal>
reply is required, so the caller will know the method
was successfully processed.
</para>

<para>
The <literal>METHOD_RETURN</literal> or
<literal>ERROR</literal> reply message must have the
<literal>REPLY_SERIAL</literal>
header field.
</para>

<para>
If a <literal>METHOD_CALL</literal> message has the flag
<literal>NO_REPLY_EXPECTED</literal>,
then as an optimization the application receiving the method
call may choose to omit the reply message (regardless of
whether the reply would have been
<literal>METHOD_RETURN</literal> or <literal>ERROR</literal>).
However, it is also acceptable to ignore the

<literal>NO_REPLY_EXPECTED</literal>
flag and reply anyway.
</para>

<para>
Unless a message has the flag
<literal>NO_AUTO_START</literal>, if the
destination name does not exist then a program to own the
destination
name will be started before the message is delivered. The
message
will be held until the new program is successfully started
or has
failed to start; in case of failure, an error will be
returned. This
flag is only relevant in the context of a message bus, it is
ignored
during one-to-one communication with no intermediate bus.
</para>

<sect4 id="message-protocol-types-method-apis">
<title>Mapping method calls to native APIs</title>
<para>
APIs for D-Bus may map method calls to a method call in a
specific
programming language, such as C++, or may map a method
call written
in an IDL to a D-Bus message.
</para>

<para>

In APIs of this nature, arguments to a method are often termed "in" (which implies sent in the `<literal>METHOD_CALL</literal>`), or "out" (which implies returned in the `<literal>METHOD_RETURN</literal>`). Some APIs such as CORBA also have "inout" arguments, which are both sent and received, i.e. the caller passes in a value which is modified. Mapped to D-Bus, an "inout" argument is equivalent to an "in" argument, followed by an "out" argument. You can't pass things "by reference" over the wire, so "inout" is purely an illusion of the in-process API.

Given a method with zero or one return values, followed by zero or more arguments, where each argument may be "in", "out", or "inout", the caller constructs a message by appending each "in" or "inout" argument, in order. "out" arguments are not represented in the caller's message.

The recipient constructs a reply by appending first the return value if any, then each "out" or "inout" argument, in order. "in" arguments are not represented in the reply message.

Error replies are normally mapped to exceptions in languages that have exceptions.

In converting from native APIs to D-Bus, it is perhaps nice to map D-Bus naming conventions ("FooBar") to native conventions such as "fooBar" or "foo_bar" automatically. This is OK as long as you can say that the native API is one that was specifically written for D-Bus. It makes the most sense when writing object implementations that will be exported over the bus. Object proxies used to invoke remote D-Bus objects probably need the ability to call any D-Bus method, and thus a magic name mapping like this could be a problem.

</para>
<para>
This specification doesn't require anything of native API
bindings;
the preceding is only a suggested convention for
consistency
among bindings.
</para>
</sect4>
</sect3>

<sect3 id="message-protocol-types-signal">
<title>Signal Emission</title>
<para>
Unlike method calls, signal emissions have no replies.
A signal emission is simply a single message of type
<literal>SIGNAL</literal>.
It must have three header fields: <literal>PATH</literal>
giving the object
the signal was emitted from, plus
<literal>INTERFACE</literal> and <literal>MEMBER</literal> giving
the fully-qualified name of the signal. The
<literal>INTERFACE</literal> header is required
for signals, though it is optional for method calls.
</para>
</sect3>

<sect3 id="message-protocol-types-errors">
<title>Errors</title>
<para>
Messages of type <literal>ERROR</literal> are most commonly
replies
to a <literal>METHOD_CALL</literal>, but may be returned in
reply
to any kind of message. The message bus for example
will return an <literal>ERROR</literal> in reply to a signal
emission if
the bus does not have enough memory to send the signal.
</para>
<para>
An <literal>ERROR</literal> may have any arguments, but if
the first
argument is a <literal>STRING</literal>, it must be an error
message.
The error message may be logged or shown to the user
in some way.
</para>
</sect3>

<sect3 id="message-protocol-types-notation">
<title>Notation in this document</title>
<para>

This document uses a simple pseudo-IDL to describe particular method calls and signals. Here is an example of a method call:

```
<programlisting>
    org.freedesktop.DBus.StartServiceByName (in STRING name,
in UINT32 flags,
                                           out UINT32
resultcode)
```

```
</programlisting>
This means <literal>INTERFACE</literal> =
org.freedesktop.DBus, <literal>MEMBER</literal> = StartServiceByName,
<literal>METHOD_CALL</literal> arguments are
<literal>STRING</literal> and <literal>UINT32</literal>,
<literal>METHOD_RETURN</literal> argument
is <literal>UINT32</literal>. Remember that the
<literal>MEMBER</literal> field can't contain any '.' (period)
characters so it's known that the last part of the name in
the "IDL" is the member name.
```

```
</para>
<para>
    In C++ that might end up looking like this:
    <programlisting>
        unsigned int org::freedesktop::DBus::StartServiceByName
(const char *name,
```

```
unsigned int flags);
    </programlisting>
    or equally valid, the return value could be done as an
argument:
    <programlisting>
        void org::freedesktop::DBus::StartServiceByName (const
char *name,
                                                         unsigned
int flags,
                                                         unsigned
int *resultcode);
    </programlisting>
```

It's really up to the API designer how they want to make this look. You could design an API where the namespace wasn't used in C++, using STL or Qt, using varargs, or whatever you wanted.

```
</para>
<para>
    Signals are written as follows:
    <programlisting>
        org.freedesktop.DBus.NameLost (STRING name)
    </programlisting>
    Signals don't specify "in" vs. "out" because only
    a single direction is possible.
</para>
<para>
```

It isn't especially encouraged to use this lame pseudo-IDL in actual API implementations; you might use the native notation for the language you're using, or you might use COM or CORBA IDL, for example.

```
</para>  
</sect3>  
</sect2>
```

```
<sect2 id="message-protocol-handling-invalid">  
  <title>Invalid Protocol and Spec Extensions</title>
```

```
  <para>  
    For security reasons, the D-Bus protocol should be strictly  
parsed and validated, with the exception of defined extension points. Any  
invalid protocol or spec violations should result in immediately  
dropping the connection without notice to the other end. Exceptions should  
be carefully considered, e.g. an exception may be warranted for a  
well-understood idiosyncrasy of a widely-deployed  
implementation. In cases where the other end of a connection is 100% trusted and  
known to be friendly, skipping validation for performance reasons could  
also make sense in certain cases.  
  </para>
```

```
  <para>  
    Generally speaking violations of the "must" requirements in  
this spec should be considered possible attempts to exploit security,  
and violations of the "should" suggestions should be considered legitimate  
(though perhaps they should generate an error in some cases).  
  </para>
```

```
  <para>  
    The following extension points are built in to D-Bus on  
purpose and must not be treated as invalid protocol. The extension points are  
intended for use by future versions of this spec, they are not intended  
for third parties. At the moment, the only way a third party could  
extend D-Bus
```

without breaking interoperability would be to introduce a way to negotiate new feature support as part of the auth protocol, using EXTENSION_-prefixed commands. There is not yet a standard way to negotiate features.

<itemizedlist>
<listitem>
<para>
In the authentication protocol (see <xref linkend="auth-protocol"/>) unknown commands result in an ERROR rather than a disconnect. This enables future extensions to the protocol. Commands starting with EXTENSION_ are reserved for third parties.

</para>
</listitem>
<listitem>
<para>
The authentication protocol supports pluggable auth mechanisms.

</para>

```

```
    <title>Protocol Overview</title>
```

```
    <para>
```

```
      The protocol is a line-based protocol, where each line ends
with
```

```
      \r\n. Each line begins with an all-caps ASCII command name
containing
```

```
      only the character range [A-Z_], a space, then any arguments
for the
```

```
      command, then the \r\n ending the line. The protocol is
      case-sensitive. All bytes must be in the ASCII character set.
```

```
      Commands from the client to the server are as follows:
```

```
      <itemizedlist>
```

```
      <listitem><para>AUTH [mechanism] [initial-
response]</para></listitem>
```

```
      <listitem><para>CANCEL</para></listitem>
```

```
      <listitem><para>BEGIN</para></listitem>
```

```
      <listitem><para>DATA &lt;data in hex
encoding&gt;</para></listitem>
```

```
      <listitem><para>ERROR [human-readable error
explanation]</para></listitem>
```

```
      <listitem><para>NEGOTIATE_UNIX_FD</para></listitem>
```

```
    </itemizedlist>
```

From server to client are as follows:

```
<itemizedlist>
  <listitem><para>REJECTED &lt;space-separated list of mechanism
names&gt;</para></listitem>
  <listitem><para>OK &lt;GUID in hex&gt;</para></listitem>
  <listitem><para>DATA &lt;data in hex
encoding&gt;</para></listitem>
  <listitem><para>ERROR</para></listitem>
  <listitem><para>AGREE_UNIX_FD</para></listitem>
</itemizedlist>
```

```
</para>
<para>
  Unofficial extensions to the command set must begin with the
letters
```

```
  "EXTENSION_", to avoid conflicts with future official
commands.
```

```
  For example, "EXTENSION_COM_MYDOMAIN_DO_STUFF".
```

  <title>AUTH command</title>
  <para>
    If an AUTH command has no arguments, it is a request to list
    available mechanisms. The server must respond with a REJECTED
    command listing the mechanisms it understands, or with an
error.
  </para>
  <para>
    If an AUTH command specifies a mechanism, and the server
supports
    said mechanism, the server should begin exchanging SASL
    challenge-response data with the client using DATA commands.
  </para>
  <para>
    If the server does not support the mechanism given in the AUTH
mechanisms
    command, it must send either a REJECTED command listing the
    mechanisms it does support, or an error.
  </para>
  <para>
    If the [initial-response] argument is provided, it is intended
for use
    with mechanisms that have no initial challenge (or an empty
initial
    challenge), as if it were the argument to an initial DATA
command. If
    the selected mechanism has an initial challenge and [initial-
response]
    was provided, the server should reject authentication by
sending
    REJECTED.
  </para>
  <para>
    If authentication succeeds after exchanging DATA commands,
    an OK command must be sent to the client.
  </para>
  <para>
    The first octet received by the server after the \r\n of the
BEGIN
    command from the client must be the first octet of the
    authenticated/encrypted stream of D-Bus messages.
  </para>
  <para>
    If BEGIN is received by the server, the first octet received
    by the client after the \r\n of the OK command must be the
    first octet of the authenticated/encrypted stream of D-Bus
    messages.
  </para>
</sect2>
<sect2 id="auth-command-cancel">
  <title>CANCEL Command</title>
```

<para>
At any time up to sending the BEGIN command, the client may
send a CANCEL command. On receiving the CANCEL command, the server
must send a REJECTED command and abort the current authentication
exchange.

</para>

</sect2>

<sect2 id="auth-command-data">

<title>DATA Command</title>

<para>

The DATA command may come from either client or server, and
contains a hex-encoded block of data to be interpreted
according to the SASL mechanism in use.

</para>

<para>

Some SASL mechanisms support sending an "empty string";
FIXME we need some way to do this.

</para>

</sect2>

<sect2 id="auth-command-begin">

<title>BEGIN Command</title>

<para>

The BEGIN command acknowledges that the client has received an
OK command from the server, and that the stream of messages
is about to begin.

</para>

<para>

The first octet received by the server after the \r\n of the
BEGIN command from the client must be the first octet of the
authenticated/encrypted stream of D-Bus messages.

</para>

</sect2>

<sect2 id="auth-command-rejected">

<title>REJECTED Command</title>

<para>

The REJECTED command indicates that the current authentication
exchange has failed, and further exchange of DATA is
inappropriate.

The client would normally try another mechanism, or try
providing different responses to challenges.

</para><para>

Optionally, the REJECTED command has a space-separated list of
available auth mechanisms as arguments. If a server ever

provides

a list of supported mechanisms, it must provide the same list
each time it sends a REJECTED message. Clients are free to
ignore all lists received after the first.

</para>

</sect2>

<sect2 id="auth-command-ok">

<title>OK Command</title>

<para>

The OK command indicates that the client has been authenticated. The client may now proceed with negotiating Unix file descriptor passing. To do that it shall send NEGOTIATE_UNIX_FD to the server.

</para>

<para>

Otherwise, the client must respond to the OK command by sending a BEGIN command, followed by its stream of messages, or by disconnecting. The server must not accept additional commands using this protocol after the BEGIN command has been received. Further communication will be a stream of D-Bus messages (optionally encrypted, as negotiated) rather than this protocol.

</para>

<para>

If a client sends BEGIN the first octet received by the client after the `\r\n` of the OK command must be the first octet of the authenticated/encrypted stream of D-Bus messages.

</para>

<para>

The OK command has one argument, which is the GUID of the server.

See [addresses](#) for more on server GUIDs.

</para>

</sect2>

<sect2 id="auth-command-error">

<title>ERROR Command</title>

<para>

The ERROR command indicates that either server or client did not know a command, does not accept the given command in the current context, or did not understand the arguments to the command.

This allows the protocol to be extended; a client or server can send a command present or permitted only in new protocol versions, and if an ERROR is received instead of an appropriate response, fall back to using some other technique.

</para>

<para>

If an ERROR is sent, the server or client that sent the error must continue as if the command causing the ERROR had never been

received. However, the the server or client receiving the error should try something other than whatever caused the error; if only canceling/rejecting the authentication.

If the D-Bus protocol changes incompatibly at some future time, applications implementing the new protocol would probably be able to check for support of the new protocol by sending a new command and receiving an ERROR from applications that don't understand it. Thus the ERROR feature of the auth protocol is an escape hatch that lets us negotiate extensions or changes to the D-Bus protocol in the future.

NEGOTIATE_UNIX_FD Command

The NEGOTIATE_UNIX_FD command indicates that the client supports Unix file descriptor passing. This command may only be sent after the connection is authenticated, i.e. after OK was received by the client. This command may only be sent on transports that support Unix file descriptor passing.

On receiving NEGOTIATE_UNIX_FD the server must respond with either AGREE_UNIX_FD or ERROR. It shall respond the former if the transport chosen supports Unix file descriptor passing and the server supports this feature. It shall respond the latter if the transport does not support Unix file descriptor passing, the server does not support this feature, or the server decides not to enable file descriptor passing due to security or other reasons.

AGREE_UNIX_FD Command

The AGREE_UNIX_FD command indicates that the server supports Unix file descriptor passing. This command may only be sent after the connection is authenticated, and the client sent NEGOTIATE_UNIX_FD to enable Unix file descriptor passing. This command may only be sent on transports that support Unix file descriptor passing.

On receiving AGREE_UNIX_FD the client must respond with BEGIN,

followed by its stream of messages, or by disconnecting. The server must not accept additional commands using this protocol after the BEGIN command has been received. Further communication will be a stream of D-Bus messages (optionally encrypted, as negotiated) rather than this protocol.

</para>

</sect2>

<sect2 id="auth-command-future">

<title>Future Extensions</title>

<para>

Future extensions to the authentication and negotiation protocol are possible. For that new commands may be introduced. If a client or server receives an unknown command it shall respond with ERROR and not consider this fatal. New commands may be introduced both before, and after authentication, i.e. both before and after the OK command.

<sect2 id="auth-states">

<title>Authentication state diagrams</title>

<para>

This section documents the auth protocol in terms of a state machine for the client and the server. This is probably the most robust way to implement the protocol.

</para>

<sect3 id="auth-states-client">

<title>Client states</title>

<para>

To more precisely describe the interaction between the protocol state machine and the authentication mechanisms the following notation is used: MECH(CHALL) means that the server challenge CHALL was fed to the mechanism MECH, which returns one of

<itemizedlist>

<listitem>

<para>

CONTINUE(RESP) means continue the auth conversation and send RESP as the response to the server;

</para>

</listitem>

<listitem>

<para>

OK(Resp) means that after sending Resp to the server the client side of the auth conversation is finished and the server should return "OK";

</para>

</listitem>

<listitem>

<para>

ERROR means that CHALL was invalid and could not be processed.

</para>

</listitem>

</itemizedlist>

Both Resp and CHALL may be empty.

</para>

<para>

The Client starts by getting an initial response from the default mechanism and sends AUTH MECH Resp, or AUTH MECH if the mechanism did not provide an initial response. If the mechanism returns CONTINUE, the client starts in state *WaitingForData*, if the mechanism returns OK the client starts in state *WaitingForOK*.

</para>

<para>

The client should keep track of available mechanisms and which it mechanisms it has already attempted. This list is used to decide which AUTH command to send. When the list is exhausted, the client should give up and close the connection.

</sect2>
```

```
</para>
</listitem>
<listitem>
  <para>
    The client locates the cookie and generates its own
    randomly-generated challenge string. The client then
concatenates
    the server's decoded challenge, a ":" character, its
own challenge,
    another ":" character, and the cookie. It computes the
SHA-1 hash
    of this composite string as a hex digest. It
concatenates the
    client's challenge string, a space character, and the
SHA-1 hex
    digest, hex-encodes the result and sends it back to
the server.
  </para>
</listitem>
<listitem>
  <para>
    The server generates the same concatenated string used
by the
    client and computes its SHA-1 hash. It compares the
hash with
    the hash received from the client; if the two hashes
match, the
    client is authenticated.
  </para>
</listitem>
</itemizedlist>
</para>
<para>
  Each server has a "cookie context," which is a name that
identifies a
  set of cookies that apply to that server. A sample context
might be
  "org_freedesktop_session_bus". Context names must be valid
ASCII,
  nonzero length, and may not contain the characters slash
  ("/"),
  backslash ("\\"), space (" "), newline ("\n"), carriage
return ("\r"),
  tab ("\t"), or period ("."). There is a default context,
  "org_freedesktop_general" that's used by servers that do not
specify
  otherwise.
</para>
<para>
  Cookies are stored in a user's home directory, in the
directory
  <filename>~/.dbus-keyrings/</filename>. This directory must
```

not be readable or writable by other users. If it is, clients and servers must ignore it. The directory contains cookie files named after the cookie context.

</para>

<para>

A cookie file contains one cookie per line. Each line has three space-separated fields:

<itemizedlist>

<listitem>

<para>

integer and The cookie ID number, which must be a non-negative integer and may not be used twice in the same file.

</para>

</listitem>

<listitem>

<para>

epoch The cookie's creation time, in UNIX seconds-since-the-epoch format.

</para>

</listitem>

<listitem>

<para>

bytes. The cookie increases The cookie itself, a hex-encoded random block of bytes. The cookie may be of any length, though obviously security increases as the length increases.

</para>

</listitem>

</itemizedlist>

</para>

<para>

Only server processes modify the cookie file.

They must do so with this procedure:

<itemizedlist>

<listitem>

<para>

name of the file creation reasonable existing lock real file Create a lockfile name by appending ".lock" to the cookie file. The server should attempt to create this using <literal>O_CREAT | O_EXCL</literal>. If file fails, the lock fails. Servers should retry for a period of time, then they may choose to delete an existing lock to keep users from having to manually delete a stale lock. <footnote><para>Lockfiles are used instead of

```

locking      locking <literal>fcntl()</literal> because real
locking      implementations are still flaky on network
              filesystems.</para></footnote>
              </para>
              </listitem>
              <listitem>
                <para>
the cookie    Once the lockfile has been created, the server loads
              file. It should then delete any cookies that are old
              (the
              timeout can be fairly short), or more than a
reasonable   time in the future (so that cookies never accidentally
              become permanent, if the clock was set far into the
future       at some point). If no recent keys remain, the
              server may generate a new key.
              </para>
              </listitem>
              <listitem>
                <para>
              The pruned and possibly added-to cookie file
              must be resaved atomically (using a temporary
              file which is rename()'d).
              </para>
              </listitem>
              <listitem>
                <para>
              The lock must be dropped by deleting the lockfile.
              </para>
              </listitem>

            </para>
            <para>
              Clients need not lock the file in order to load it,
              because servers are required to save the file atomically.
            </para>
          </sect3>
        </sect2>
      </sect1>
    <sect1 id="addresses">
      <title>Server Addresses</title>
      <para>
        Server addresses consist of a transport name followed by a
colon, and
        then an optional, comma-separated list of keys and values in the
form key=value.
        Each value is escaped.
      </para>
      <para>

```

For example:
<programlisting>unix:path=/tmp/dbus-test</programlisting>
Which is the address to a unix socket with the path /tmp/dbus-test.

</para>
<para>
Value escaping is similar to URI escaping but simpler.

<itemizedlist>
<listitem>
<para>
The set of optionally-escaped bytes is:
<literal>[0-9A-Za-z_-.\\]</literal>. To escape, each
<emphasis>byte</emphasis> (note, not character) which is
not in the
ASCII
in hex.
The hex value must always be two digits, even if the first
digit is
desired.
zero. The optionally-escaped bytes may be escaped if
desired.

</para>
</listitem>
<listitem>
<para>
To unescape, append each byte in the value; if a byte is
an ASCII
following
percent (<literal>%</literal>) character then append the
hex value instead. It is an error if a
<literal>%</literal> byte
does not have two hex digits following. It is an error if
a
non-optionally-escaped byte is seen unescaped.

</para>
</listitem>
</itemizedlist>
The set of optionally-escaped bytes is intended to preserve
address
readability and convenience.

</para>
<para>
A server may specify a key-value pair with the key
<literal>guid</literal>
and the value a hex-encoded 16-byte sequence. <xref
linkend="uuids"/>
describes the format of the <literal>guid</literal> field. If
present,
this UUID may be used to distinguish one server address from
another. A

server should use a different UUID for each address it listens on. For example, if a message bus daemon offers both UNIX domain socket and TCP connections, but treats clients the same regardless of how they connect, those two connections are equivalent post-connection but should have distinct UUIDs to distinguish the kinds of connection.

The intent of the address UUID feature is to allow a client to avoid opening multiple identical connections to the same server, by allowing the client to check whether an address corresponds to an already-existing connection. Comparing two addresses is insufficient, because addresses can be recycled by distinct servers, and equivalent addresses may look different if simply compared as strings (for example, the host in a TCP address can be given as an IP address or as a hostname).

Note that the address key is `guid` even though the rest of the API and documentation says "UUID," for historical reasons.

[FIXME clarify if attempting to connect to each is a requirement or just a suggestion]
When connecting to a server, multiple server addresses can be separated by a semi-colon. The library will then try to connect to the first address and if that fails, it'll try to connect to the next one specified, and so forth. For example

```
<programlisting>unix:path=/tmp/dbus-test;unix:path=/tmp/dbus-test2</programlisting>
```

</sect1>

<sect1 id="transports">
<title>Transports</title>
<para>
[FIXME we need to specify in detail each transport and its possible arguments]

Current transports include: unix domain sockets (including abstract namespace on linux), launchd, systemd, TCP/IP, an executed subprocess and a debug/testing transport using in-process pipes. Future possible transports include one that tunnels over X11 protocol.

<sect2 id="transports-unix-domain-sockets">

<title>Unix Domain Sockets</title>

<para>

Unix domain sockets can be either paths in the file system or on Linux kernels, they can be abstract which are similar to paths but do not show up in the file system.

</para>

<para>

When a socket is opened by the D-Bus library it truncates the path name right before the first trailing Nul byte. This is true for both normal paths and abstract paths. Note that this is a departure from previous versions of D-Bus that would create sockets with a fixed length path name. Names which were shorter than the fixed length would be padded by Nul bytes.

</para>

<para>

Unix domain sockets are not available on Windows.

<sect2 id="transports-nonce-tcp-sockets">
```

```
<title>Nonce-secured TCP Sockets</title>
```

```
<para>
```

The nonce-tcp transport provides a secured TCP transport, using a simple authentication mechanism to ensure that only clients with read access to a certain location in the filesystem can connect to the server.

The server writes a secret, the nonce, to a file and an incoming client connection is only accepted if the client sends the nonce right after the connect. The nonce mechanism requires no setup and is orthogonal to the higher-level authentication mechanisms described in the Authentication section.

```
</para>
```

```
<para>
```

On start, the server generates a random 16 byte nonce and writes it to a file in the user's temporary directory. The nonce file location is published as part of the server's D-Bus address using the "noncefile" key-value pair.

After an accept, the server reads 16 bytes from the socket. If the read bytes do not match the nonce stored in the nonce file, the server MUST immediately drop the connection.

If the nonce match the received byte sequence, the client is accepted and the transport behaves like an unsecured tcp transport.

```
</para>
```

```
<para>
```

After a successful connect to the server socket, the client MUST read the nonce from the file published by the server via the noncefile= key-value pair and send it over the socket. After that, the transport behaves like an unsecured tcp transport.

```
</para>
```

```

```

```
<title>Windows implementation</title>
```

```
<para>
```

On start, the server opens a platform specific transport, creates a mutex and a shared memory section containing the related session bus address.

This mutex will be inspected by the dbus client library to detect a

running dbus session bus. The access to the mutex and the shared memory

section are protected by global locks.

```
</para>
```

```
<para>
```

In the recent implementation the autolaunch transport uses a tcp transport

on localhost with a port choosen from the operating system.

This detail may

change in the future.

</para>
<para>
Disclaimer: The recent implementation is in an early state and
may not
work in all circumstances and/or may have security issues.
Because of this
the implementation is not documented yet.
</para>
</sect3>
</sect2>
</sect1>

<sect1 id="uuids">
<title>UUIDs</title>
<para>
A working D-Bus implementation uses universally-unique IDs in
two places.
First, each server address has a UUID identifying the address,
as described in <xref linkend="addresses"/>. Second, each
operating
system kernel instance running a D-Bus client or server has a
UUID
identifying that kernel, retrieved by invoking the method
org.freedesktop.DBus.Peer.GetMachineId() (see <xref
linkend="standard-interfaces-peer"/>).
</para>
<para>
The term "UUID" in this document is intended literally, i.e. an
identifier that is universally unique. It is not intended to
refer to
RFC4122, and in fact the D-Bus UUID is not compatible with that
RFC.
</para>
<para>
The UUID must contain 128 bits of data and be hex-encoded. The
hex-encoded string may not contain hyphens or other non-hex-
digit
characters, and it must be exactly 32 characters long. To
generate a
UUID, the current reference implementation concatenates 96 bits
of random
data followed by the 32-bit time in seconds since the UNIX epoch
(in big
endian byte order).
</para>
<para>
It would also be acceptable and probably better to simply
generate 128
bits of random data, as long as the random number generator is
of high
quality. The timestamp could conceivably help if the random bits
are not

very random. With a quality random number generator, collisions are extremely unlikely even with only 96 bits, so it's somewhat academic.

</para>

<para>

Implementations should, however, stick to random data for the first 96 bits of the UUID.

</para>

</sect1>

<sect1 id="standard-interfaces">

<title>Standard Interfaces</title>

<para>

See <xref linkend="message-protocol-types-notation"/> for details on

the notation used in this section. There are some standard interfaces

that may be useful across various D-Bus applications.

</para>

<sect2 id="standard-interfaces-peer">

<title><literal>org.freedesktop.DBus.Peer</literal></title>

<para>

The <literal>org.freedesktop.DBus.Peer</literal> interface has two methods:

<programlisting>

org.freedesktop.DBus.Peer.Ping ()

org.freedesktop.DBus.Peer.GetMachineId (out STRING machine_uuid)

</programlisting>

</para>

<para>

On receipt of the <literal>METHOD_CALL</literal> message <literal>org.freedesktop.DBus.Peer.Ping</literal>, an application should do

nothing other than reply with a

<literal>METHOD_RETURN</literal> as

usual. It does not matter which object path a ping is sent to. The

reference implementation handles this method automatically.

</para>

<para>

On receipt of the <literal>METHOD_CALL</literal> message <literal>org.freedesktop.DBus.Peer.GetMachineId</literal>, an application should

reply with a <literal>METHOD_RETURN</literal> containing a hex-encoded

UUID representing the identity of the machine the process is running on.

This UUID must be the same for all processes on a single system at least

until that system next reboots. It should be the same across reboots if possible, but this is not always possible to implement and is not

guaranteed.

It does not matter which object path a GetMachineId is sent to. The

reference implementation handles this method automatically.

</para>

<para>

The UUID is intended to be per-instance-of-the-operating-system, so may represent

a virtual machine running on a hypervisor, rather than a physical machine.

Basically if two processes see the same UUID, they should also see the same

shared memory, UNIX domain sockets, process IDs, and other features that require

a running OS kernel in common between the processes.

</para>

<para>

The UUID is often used where other programs might use a hostname. Hostnames

can change without rebooting, however, or just be "localhost" - so the UUID

is more robust.

</para>

<para>

<xref linkend="uuids"/> explains the format of the UUID.

</para>

</sect2>

<sect2 id="standard-interfaces-introspectable">

<title><literal>org.freedesktop.DBus.Introspectable</literal></title>

<para>

This interface has one method:

<programlisting>

org.freedesktop.DBus.Introspectable.Introspect (out STRING xml_data)

</programlisting>

</para>

<para>

Objects instances may implement

<literal>Introspect</literal> which returns an XML description of

the object, including its interfaces (with signals and methods), objects

below it in the object path tree, and its properties.

</para>

<para>

`<xref linkend="introspection-format"/>` describes the format of this XML string.

`</para>`

`</sect2>`

`<sect2 id="standard-interfaces-properties">`

`<title><literal>org.freedesktop.DBus.Properties</literal></title>`

`<para>`

Many native APIs will have a concept of object `<firstterm>properties</firstterm>` or `<firstterm>attributes</firstterm>`. These can be exposed via the

`<literal>org.freedesktop.DBus.Properties</literal>` interface.

`</para>`

`<para>`

`<programlisting>`

```
org.freedesktop.DBus.Properties.Get (in STRING
interface_name,
                                     in STRING
property_name,
                                     out VARIANT value);
org.freedesktop.DBus.Properties.Set (in STRING
interface_name,
                                     in STRING
property_name,
                                     in VARIANT value);
org.freedesktop.DBus.Properties.GetAll (in STRING
interface_name,
                                     out
DICT<STRING,VARIANT> props);
```

`</programlisting>`

`</para>`

`<para>`

It is conventional to give D-Bus property names consisting of capitalized words without punctuation ("CamelCase"), like `<link linkend="message-protocol-names-member">member names</link>`.

For instance, the GObject property `<literal>connection-status</literal>` or the Qt property `<literal>connectionStatus</literal>` could be represented on D-

Bus

as `<literal>ConnectionStatus</literal>`.

`</para>`

`<para>`

Strictly speaking, D-Bus property names are not required to follow

the same naming restrictions as member names, but D-Bus property

names that would not be valid member names (in particular, GObject-style dash-separated property names) can cause interoperability

problems and should be avoided.

</para>

<para>

The available properties and whether they are writable can be determined

by calling

<literal>org.freedesktop.DBus.Introspectable.Introspect</literal>, see <xref linkend="standard-interfaces-introspectable"/>.

</para>

<para>

An empty string may be provided for the interface name; in this case,

if there are multiple properties on an object with the same name,

the results are undefined (picking one by according to an arbitrary

deterministic rule, or returning an error, are the reasonable possibilities).

</para>

<para>

If one or more properties change on an object, the

<literal>org.freedesktop.DBus.Properties.PropertiesChanged</literal> signal may be emitted (this signal was added in 0.14):

</para>

<para>

<programlisting>

```
org.freedesktop.DBus.Properties.PropertiesChanged
```

```
(STRING interface_name,
```

```
DICTIONARY<STRING,VARIANT> changed_properties,
```

```
ARRAY<STRING> invalidated_properties);
```

</programlisting>

</para>

<para>

where <literal>changed_properties</literal> is a dictionary containing the changed properties with the new values and <literal>invalidated_properties</literal> is an array of properties that changed but the value is not conveyed.

</para>

<para>

Whether the <literal>PropertiesChanged</literal> signal is supported can be determined by calling

<literal>org.freedesktop.DBus.Introspectable.Introspect</literal>.

Note

that the signal may be supported for an object but it may differ how whether and how it is used on a per-property basis (for e.g. performance or security reasons). Each property (or the parent interface) must be annotated with the

`org.freedesktop.DBus.Property.EmitsChangedSignal` annotation to convey this (usually the default value `true` is sufficient meaning that the annotation does not need to be used). See [introspection-format](#) for details on this annotation.

`standard-interfaces-objectmanager`

`org.freedesktop.DBus.ObjectManager`

An API can optionally make use of this interface for one or more sub-trees of objects. The root of each sub-tree implements this interface so other applications can get all objects, interfaces and properties in a single method call. It is appropriate to use this interface if users of the tree of objects are expected to be interested in all interfaces of all objects in the tree; a more granular API should be used if users of the objects are expected to be interested in a small subset of the objects, a small subset of their interfaces, or both.

The method that applications can use to get all objects and properties is `GetManagedObjects`:

```
<programlisting>
```

```
org.freedesktop.DBus.ObjectManager.GetManagedObjects (out
DICT<OBJPATH, DICT<STRING, DICT<STRING, VARIANT>>>>
objpath_interfaces_and_properties);
```

```
</programlisting>
```

The return value of this method is a dict whose keys are object paths. All returned object paths are children of the object path implementing this interface, i.e. their object paths start with the ObjectManager's object path plus `'/'`.

Each value is a dict whose keys are interfaces names. Each value in this inner dict is the same dict that would be returned by the [standard-interfaces-properties](#)

`org.freedesktop.DBus.Properties.GetAll()` method for that combination of object path and interface. If an interface has no properties, the empty dict is returned.

<para>

Changes are emitted using the following two signals:

</para>

<para>

<programlisting>

```
org.freedesktop.DBus.ObjectManager.InterfacesAdded (OBJPATH
object_path,
```

```
    DICT&lt;STRING, DICT&lt;STRING, VARIANT&gt;&gt;
    interfaces_and_properties);
```

```
    org.freedesktop.DBus.ObjectManager.InterfacesRemoved
    (OBJPATH object_path,
```

```
    ARRAY&lt;STRING&gt; interfaces);
```

</programlisting>

</para>

<para>

The <literal>InterfacesAdded</literal> signal is emitted when either a new object is added or when an existing object gains one or more interfaces. The <literal>InterfacesRemoved</literal> signal is emitted whenever an object is removed or it loses one or more interfaces. The second parameter of the <literal>InterfacesAdded</literal> signal contains a dict with the interfaces and properties (if any) that have been added to the given object path. Similarly, the second parameter of the <literal>InterfacesRemoved</literal> signal contains an array of the interfaces that were removed. Note that changes on properties on existing interfaces are not reported using this interface - an application should also monitor the existing

<link

linkend="standard-interfaces-properties">PropertiesChanged</link>
signal on each object.

</para>

<para>

Applications SHOULD NOT export objects that are children of an object (directly or otherwise) implementing this interface but which are not returned in the reply from the <literal>GetManagedObjects()</literal> method of this interface on the given object.

</para>

<para>

The intent of the <literal>ObjectManager</literal> interface is to make it easy to write a robust client implementation. The trivial client implementation only needs to make two method calls:

</para>

<para>

<programlisting>

```
org.freedesktop.DBus.AddMatch (bus_proxy,
```

```

"type='signal',name='org.example.App',path_namespace='/org/example/App
');
    objects =
org.freedesktop.DBus.ObjectManager.GetManagedObjects (app_proxy);
    </programlisting>
</para>
<para>
    on the message bus and the remote application's
    <literal>ObjectManager</literal>, respectively. Whenever a new
    remote object is created (or an existing object gains a new
    interface), the <literal>InterfacesAdded</literal> signal is
    emitted, and since this signal contains all properties for the
    interfaces, no calls to the
    <literal>org.freedesktop.Properties</literal> interface on the
    remote object are needed. Additionally, since the initial
    <literal>AddMatch()</literal> rule already includes signal
    messages from the newly created child object, no new
    <literal>AddMatch()</literal> call is needed.
</para>

<para>
    <emphasis>
        The <literal>org.freedesktop.DBus.ObjectManager</literal>
        interface was added in version 0.17 of the D-Bus
        specification.
    </emphasis>
</para>
</sect2>

<sect1 id="introspection-format">
    <title>Introspection Data Format</title>
    <para>
        As described in <xref linkend="standard-interfaces-
        introspectable"/>,
        objects may be introspected at runtime, returning an XML string
        that describes the object. The same XML format may be used in
        other contexts as well, for example as an "IDL" for generating
        static language bindings.
    </para>
    <para>
        Here is an example of introspection data:
        <programlisting>
            &lt;!DOCTYPE node PUBLIC "-//freedesktop//DTD D-BUS Object
            Introspection 1.0//EN"
"http://www.freedesktop.org/standards/dbus/1.0/introspect.dtd">
            &lt;node name="/org/freedesktop/sample_object">
                &lt;interface name="org.freedesktop.SampleInterface">
                    &lt;method name="Frobate">
                        &lt;arg name="foo" type="i" direction="in"/>

```

```

        <arg name="bar" type="s" direction="out"/>
        <arg name="baz" type="a{us}" direction="out"/>
        <annotation name="org.freedesktop.DBus.Deprecated"
value="true"/>
    </method>
    <method name="Bazify">
        <arg name="bar" type="(iiu)" direction="in"/>
        <arg name="bar" type="v" direction="out"/>
    </method>
    <method name="Mogrify">
        <arg name="bar" type="(iiav)" direction="in"/>
    </method>
    <signal name="Changed">
        <arg name="new_value" type="b"/>
    </signal>
    <property name="Bar" type="y" access="readwrite"/>
</interface>
<node name="child_of_sample_object"/>
<node name="another_child_of_sample_object"/>
</node>
</programlisting>

```

</para>

<para>

A more formal DTD and spec needs writing, but here are some quick notes.

<itemizedlist>

<listitem>

<para>

Only the root <node> element can omit the node name, as it's known to be the object that was introspected. If the root <node> does have a name attribute, it must be an absolute object path. If child <node> have object paths, they must be relative.

</para>

</listitem>

<listitem>

<para>

If a child <node> has any sub-elements, then they must represent a complete introspection of the child. If a child <node> is empty, then it may or may not have sub-elements; the child must be introspected in order to find out. The intent is that if an object knows that its children are "fast" to introspect it can go ahead and return their information, but otherwise it can omit it.

</para>

</listitem>

<listitem>

<para>

The direction element on `<arg>` may be omitted, in which case it defaults to "in" for method calls and "out" for signals. Signals only allow "out" so while direction may be specified, it's pointless.

`</para>`

`</listitem>`

`<listitem>`

`<para>`

The possible directions are "in" and "out", unlike CORBA there is no "inout"

`</para>`

`</listitem>`

`<listitem>`

`<para>`

The possible property access flags are "readwrite", "read", and "write"

`</para>`

`</listitem>`

`<listitem>`

`<para>`

Multiple interfaces can of course be listed for one `<node>`.

`</para>`

`</listitem>`

`<listitem>`

`<para>`

The "name" attribute on arguments is optional.

`</para>`

`</listitem>`

`</itemizedlist>`

`</para>`

`<para>`

Method, interface, property, and signal elements may have "annotations", which are generic key/value pairs of metadata. They are similar conceptually to Java's annotations and C# attributes.

Well-known annotations:

<sect1 id="message-bus">
    <title>Message Bus Specification</title>

```

```
<sect2 id="message-bus-overview">
  <title>Message Bus Overview</title>
  <para>
    The message bus accepts connections from one or more
applications.
    Once connected, applications can exchange messages with other
    applications that are also connected to the bus.
  </para>
  <para>
    In order to route messages among connections, the message bus
keeps a
    mapping from names to connections. Each connection has one
    unique-for-the-lifetime-of-the-bus name automatically
assigned.
    Applications may request additional names for a connection.
Additional
    names are usually "well-known names" such as
    "org.freedesktop.TextEditor". When a name is bound to a
connection,
    that connection is said to <firstterm>own</firstterm> the
name.
  </para>
  <para>
    The bus itself owns a special name,
<literal>org.freedesktop.DBus</literal>.
    This name routes messages to the bus, allowing applications to
make
    administrative requests. For example, applications can ask the
bus
    to assign a name to a connection.
  </para>
  <para>
    Each name may have <firstterm>queued owners</firstterm>. When
an
    application requests a name for a connection and the name is
already in
    use, the bus will optionally add the connection to a queue
waiting for
    the name. If the current owner of the name disconnects or
releases
    the name, the next connection in the queue will become the new
owner.
  </para>
  <para>
    This feature causes the right thing to happen if you start two
text
    editors for example; the first one may request
"org.freedesktop.TextEditor",
    and the second will be queued as a possible owner of that
name. When
    the first exits, the second will take over.
  </para>
</sect2>
```

</para>

<para>

Applications may send <firstterm>unicast messages</firstterm> to a specific recipient or to the message bus itself, or <firstterm>broadcast messages</firstterm> to all interested recipients.

See <xref linkend="message-bus-routing"/> for details.

</para>

</sect2>

<sect2 id="message-bus-names">

<title>Message Bus Names</title>

<para>

Each connection has at least one name, assigned at connection time and

returned in response to the

<literal>org.freedesktop.DBus.Hello</literal> method call.

This

automatically-assigned name is called the connection's

<firstterm>unique

name</firstterm>. Unique names are never reused for two

different

connections to the same bus.

</para>

<para>

Ownership of a unique name is a prerequisite for interaction

with

the message bus. It logically follows that the unique name is

always

the first name that an application comes to own, and the last one that it loses ownership of.

</para>

<para>

Unique connection names must begin with the character ':' (ASCII colon

character); bus names that are not unique names must not begin

with this character. (The bus must reject any attempt by an

application

to manually request a name beginning with ':'.) This

restriction

categorically prevents "spoofing"; messages sent to a unique

name

will always go to the expected connection.

</para>

<para>

When a connection is closed, all the names that it owns are deleted (or

transferred to the next connection in the queue if any).

</para>

<para>

A connection can request additional names to be associated with it using the `<literal>org.freedesktop.DBus.RequestName</literal>` message. [linkend="message-protocol-names-bus"/>](#) describes the format of a valid name. These names can be released again using the `<literal>org.freedesktop.DBus.ReleaseName</literal>` message.

</para>
<para>

```

This method call should be sent to `org.freedesktop.DBus` and asks the message bus to assign the given name to the method caller. Each name maintains a queue of possible owners, where the head of the queue is the primary or current owner of the name. Each potential owner in the queue maintains the `DBUS_NAME_FLAG_ALLOW_REPLACEMENT` and `DBUS_NAME_FLAG_DO_NOT_QUEUE` settings from its latest `RequestName` call. When `RequestName` is invoked the following occurs:

- If the method caller is currently the primary owner of the name, the `DBUS_NAME_FLAG_ALLOW_REPLACEMENT` and `DBUS_NAME_FLAG_DO_NOT_QUEUE` values are updated with the values from the new `RequestName` call, and nothing further happens.
- If the current primary owner (head of the queue) has `DBUS_NAME_FLAG_ALLOW_REPLACEMENT` set, and the invocation has the `DBUS_NAME_FLAG_REPLACE_EXISTING` flag, then the caller of `RequestName` replaces the current primary owner at the head of the queue and the current primary owner moves to the second position in the queue. If the caller of `RequestName` was in the queue previously its flags are updated with the values from

the new RequestName in addition to moving it to the head of the queue.

</para>
</listitem>

<listitem>
<para>
If replacement is not possible, and the method caller is currently in the queue but not the primary owner, its flags are updated with the values from the new RequestName call.

</para>
</listitem>

<listitem>
<para>
If replacement is not possible, and the method caller is currently not in the queue, the method caller is appended to the queue.

</para>
</listitem>

<listitem>
<para>
If any connection in the queue has DBUS_NAME_FLAG_DO_NOT_QUEUE set and is not the primary owner, it is removed from the queue. This can apply to the previous primary owner (if it was replaced) or the method caller (if it updated the DBUS_NAME_FLAG_DO_NOT_QUEUE flag while still stuck in the queue, or if it was just added to the queue with that flag set).

</para>
</listitem>

</itemizedlist>

</para>
<para>
Note that DBUS_NAME_FLAG_REPLACE_EXISTING results in "jumping the queue," even if another application already in the queue had specified DBUS_NAME_FLAG_REPLACE_EXISTING. This comes up if a primary owner that does not allow replacement goes away, and the next primary owner

does allow replacement. In this case, queued items that specified `DBUS_NAME_FLAG_REPLACE_EXISTING` *do not* automatically replace the new primary owner. In other words, `DBUS_NAME_FLAG_REPLACE_EXISTING` is not saved, it is only used at the time `RequestName` is called. This is deliberate to avoid an infinite loop anytime two applications are both `DBUS_NAME_FLAG_ALLOW_REPLACEMENT` and `DBUS_NAME_FLAG_REPLACE_EXISTING`.

The flags argument contains any of the following values logically ORed together:

Conventional Name	Value	Description
<code>DBUS_NAME_FLAG_ALLOW_REPLACEMENT</code>	0x1	

If an application A specifies this flag and succeeds in becoming the owner of the name, and another application B later calls `RequestName` with the `DBUS_NAME_FLAG_REPLACE_EXISTING` flag, then application A will lose ownership and receive a `org.freedesktop.DBus.NameLost` signal, and application B will become the new owner. If `DBUS_NAME_FLAG_ALLOW_REPLACEMENT` is not specified by application A, or `DBUS_NAME_FLAG_REPLACE_EXISTING` is not specified by application B, then application B will not replace application A as the owner.

```
<row>
<entry>DBUS_NAME_FLAG_REPLACE_EXISTING</entry>
<entry>0x2</entry>
<entry>
```

If this flag is not set the application will only become the owner of the name if there is no current owner. If this flag is set, the application will replace the current owner if the current owner specified DBUS_NAME_FLAG_ALLOW_REPLACEMENT.

```
</entry>
</row>
<row>
<entry>DBUS_NAME_FLAG_DO_NOT_QUEUE</entry>
<entry>0x4</entry>
<entry>
```

Without this flag, if an application requests a name that is already owned, the application will be placed in a queue to own the name when the current owner gives it up. If this flag is given, the application will not be placed in the queue, the request for the name will simply fail. This flag also affects behavior when an application is replaced as name owner; by default the application moves back into the waiting queue, unless this flag was provided when the application became the name owner.

</para>
</sect3>
</sect2>

<sect2 id="message-bus-routing">
    <title>Message Bus Message Routing</title>

    <para>
        Messages may have a <literal>DESTINATION</literal> field (see
<xref
        linkend="message-protocol-header-fields"/>), resulting in a
    <firstterm>unicast message</firstterm>. If the
    <literal>DESTINATION</literal> field is present, it specifies
a message
    recipient by name. Method calls and replies normally specify
this field.
    The message bus must send messages (of any type) with the
    <literal>DESTINATION</literal> field set to the specified
recipient,
    regardless of whether the recipient has set up a match rule
matching
    the message.
</para>

    <para>
        When the message bus receives a signal, if the
    <literal>DESTINATION</literal> field is absent, it is
considered to
    be a <firstterm>broadcast signal</firstterm>, and is sent to
all
    applications with <firstterm>message matching
rules</firstterm> that
    match the message. Most signal messages are broadcasts.
</para>

    <para>
        Unicast signal messages (those with a
<literal>DESTINATION</literal>
    field) are not commonly used, but they are treated like any
unicast
    message: they are delivered to the specified recipient,
    regardless of its match rules. One use for unicast signals is
to

```

avoid a race condition in which a signal is emitted before the intended recipient can call `<xref linkend="bus-messages-add-match"/>` to receive that signal: if the signal is sent directly to that recipient using a unicast message, it does not need to add a match rule at all, and there is no race condition. Another use for unicast signals, on message buses whose security policy prevents eavesdropping, is to send sensitive information which should only be visible to one recipient.

</para>

<para>
When the message bus receives a method call, if the `<literal>DESTINATION</literal>` field is absent, the call is taken to be a standard one-to-one message and interpreted by the message bus itself. For example, sending an `<literal>org.freedesktop.DBus.Peer.Ping</literal>` message with no `<literal>DESTINATION</literal>` will cause the message bus itself to reply to the ping immediately; the message bus will not make this message visible to other applications.

</para>

<para>
Continuing the `<literal>org.freedesktop.DBus.Peer.Ping</literal>` example, if the ping message were sent with a `<literal>DESTINATION</literal>` name of `<literal>com.yoyodyne.Screensaver</literal>`, then the ping would be forwarded, and the Yoyodyne Corporation screensaver application would be expected to reply to the ping.

</para>

<para>
Message bus implementations may impose a security policy which prevents certain messages from being sent or received. When a message cannot be sent or received due to a security policy, the message bus should send an error reply, unless the original message had the `<literal>NO_REPLY</literal>` flag.

</para>

<sect3 id="message-bus-routing-eavesdropping">

`<title>Eavesdropping</title>`
`<para>`
Receiving a unicast message whose
`<literal>DESTINATION</literal>`
indicates a different recipient is called
`<firstterm>eavesdropping</firstterm>`. On a message bus which
acts as
a security boundary (like the standard system bus), the
security
policy should usually prevent eavesdropping, since unicast
messages
are normally kept private and may contain security-sensitive
information.
`</para>`

`<para>`
Eavesdropping is mainly useful for debugging tools, such as
the `<literal>dbus-monitor</literal>` tool in the reference
implementation of D-Bus. Tools which eavesdrop on the
message bus
should be careful to avoid sending a reply or error in
response to
messages intended for a different client.
`</para>`

`<para>`
Clients may attempt to eavesdrop by adding match rules
(see `<xref linkend="message-bus-routing-match-rules"/>`)
containing
the `<literal>eavesdrop='true'</literal>` match. If the
message bus'
security policy does not allow eavesdropping, the match rule
can
still be added, but will not have any practical effect. For
compatibility with older message bus implementations, if
adding such
a match rule results in an error reply, the client may fall
back to
adding the same rule with the `<literal>eavesdrop</literal>`
match
omitted.
`</para>`
`</sect3>`

`<sect3 id="message-bus-routing-match-rules">`
`<title>Match Rules</title>`
`<para>`
An important part of the message bus routing protocol is match
rules. Match rules describe the messages that should be sent
to a
client, based on the contents of the message. Broadcast
signals

are only sent to clients which have a suitable match rule:
this
avoids waking up client processes to deal with signals that
are
not relevant to that client.

</para>
<para>
Messages that list a client as their
<literal>DESTINATION</literal>
do not need to match the client's match rules, and are sent
to that
client regardless. As a result, match rules are mainly used
to
receive a subset of broadcast signals.

</para>
<para>
Match rules can also be used for eavesdropping
(see <xref linkend="message-bus-routing-eavesdropping"/>),
if the security policy of the message bus allows it.

</para>
<para>
Match rules are added using the AddMatch bus method
(see <xref linkend="bus-messages-add-match"/>). Rules are
specified as a string of comma separated key/value pairs.
Excluding a key from the rule indicates a wildcard match.
For instance excluding the the member from a match rule but
adding a sender would let all messages from that sender

through.
An example of a complete rule would be

```
"type='signal',sender='org.freedesktop.DBus',interface='org.freedesktop.DBus',member='Foo',path='/bar/foo',destination=':452345.34',arg2='bar'"
```

</para>
<para>
The following table describes the keys that can be used to
create
a match rule:

The following table summarizes the D-Bus types.

    <entry>Any string</entry>
    <entry>
        <para>Argument path matches provide a specialised
form of wildcard matching for
        path-like namespaces. They can match arguments
whose type is either STRING or
        OBJECT_PATH. As with normal argument matches,
if the argument is exactly equal to the string
given in the match
        rule then the rule is satisfied. Additionally,
there is also a
        match when either the string given in the match
rule or the
        appropriate message argument ends with '/' and
is a prefix of the
        other. An example argument path match is
arg0path='/aa/bb/'. This
        would match messages with first arguments of
'/', '/aa/',
        '/aa/bb/', '/aa/bb/cc/' and '/aa/bb/cc/'. It
would not match
        messages with first arguments of '/aa/b', '/aa'
or even '/aa/bb'.</para>
        <para>This is intended for monitoring
&œdirectories&• in file system-like
        hierarchies, as used in the
<citetitle>dconf</citetitle> configuration
        system. An application interested in all nodes
in a particular hierarchy would
        monitor
<literal>arg0path='/ca/example/foo/'</literal>. Then the service could
        emit a signal with zeroth argument
<literal>"/ca/example/foo/bar"</literal> to
        represent a modification to the &œbar&•
property, or a signal with zeroth
        argument <literal>"/ca/example/"</literal> to
represent atomic modification of
        many properties within that directory, and the
interested application would be
        notified in both cases.</para>

</para>
</sect3>
</sect2>
<sect2 id="message-bus-starting-services">
<title>Message Bus Starting Services</title>
<para>
The message bus can start applications on behalf of other
applications.
In CORBA terms, this would be called
<firstterm>activation</firstterm>.
An application that can be started in this way is called a
<firstterm>service</firstterm>.
</para>
<para>
With D-Bus, starting a service is normally done by name. That
is,
applications ask the message bus to start some program that
will own a
well-known name, such as
<literal>org.freedesktop.TextEditor</literal>.

This implies a contract documented along with the name
<literal>org.freedesktop.TextEditor</literal> for which
objects

the owner of that name will provide, and what interfaces those
objects will have.

</para>

<para>

To find an executable corresponding to a particular name, the
bus daemon

looks for <firstterm>service description files</firstterm>.

Service

description files define a mapping from names to executables.

Different

kinds of message bus will look for these files in different
places, see

<xref linkend="message-bus-types"/>.

</para>

<para>

Service description files have the ".service" file
extension. The message bus will only load service description

files

ending with .service; all other files will be ignored. The

file format

is similar to that of <ulink

url="http://standards.freedesktop.org/desktop-entry-
spec/desktop-entry-spec-latest.html">desktop

entries</ulink>. All service description files must be in UTF-

8

encoding. To ensure that there will be no name collisions,
service files

must be namespaced using the same mechanism as messages and
service

names.

</para>

<para>

[FIXME the file format should be much better specified than
"similar to

.desktop entries" esp. since desktop entries are already
badly-specified. ;-)]

These sections from the specification apply to service files
as well:

<itemizedlist>

<listitem><para>General syntax</para></listitem>

<listitem><para>Comment format</para></listitem>

</itemizedlist>

<figure>

<title>Example service description file</title>

<programlisting>

Sample service description file

[D-BUS Service]

```
Names=org.freedesktop.ConfigurationDatabase;org.gnome.GConf;  
Exec=/usr/libexec/gconfd-2
```

```
</programlisting>
```

```
</figure>
```

```
</para>
```

```
<para>
```

When an application asks to start a service by name, the bus daemon tries to find a service that will own that name. It then tries to spawn the executable associated with it. If this fails, it will report an error. [FIXME what happens if two .service files offer the same service;

what kind of error is reported, should we have a way for the client to choose one?]

```
</para>
```

```
<para>
```

The executable launched will have the environment variable `<literal>DBUS_STARTER_ADDRESS</literal>` set to the address of the message bus so it can connect and request the appropriate names.

```
</para>
```

```
<para>
```

The executable being launched may want to know whether the message bus starting it is one of the well-known message buses (see [<xref linkend="message-bus-types"/>](#)). To facilitate this, the bus must also set the `<literal>DBUS_STARTER_BUS_TYPE</literal>` environment variable if it is one of the well-known buses. The currently-defined values for this variable

are `<literal>system</literal>` for the systemwide message bus, and `<literal>session</literal>` for the per-login-session

message bus. The new executable must still connect to the address given

in `<literal>DBUS_STARTER_ADDRESS</literal>`, but may assume that the resulting connection is to the well-known bus.

```
</para>
```

```
<para>
```

[FIXME there should be a timeout somewhere, either specified in the .service file, by the client, or just a global value and if the client being activated fails to connect within that timeout, an error should be sent back.]

```
</para>
```

```
<sect3 id="message-bus-starting-services-scope">
  <title>Message Bus Service Scope</title>
  <para>
    The "scope" of a service is its "per-", such as per-session,
    per-machine, per-home-directory, or per-display. The
reference
    implementation doesn't yet support starting services in a
different
    scope from the message bus itself. So e.g. if you start a
service
    on the session bus its scope is per-session.
  </para>
  <para>
    We could add an optional scope to a bus name. For example,
for
    per-(display,session pair), we could have a unique ID for
each display
    generated automatically at login and set on screen 0 by
executing a
    special "set display ID" binary. The ID would be stored in a
string of
    <literal>_DBUS_DISPLAY_ID</literal> property and would be a
    random bytes. This ID would then be used to scope names.
    Starting/locating a service could be done by ID-name pair
rather than
    only by name.
  </para>
  <para>
    Contrast this with a per-display scope. To achieve that, we
would
    want a single bus spanning all sessions using a given
display.
    So we might set a
<literal>_DBUS_DISPLAY_BUS_ADDRESS</literal>
    property on screen 0 of the display, pointing to this bus.
  </para>

user's login session may interact with one another using this message bus.

</para>

<para>

The address of the login session message bus is given in the `DBUS_SESSION_BUS_ADDRESS` environment variable. If that variable is not set, applications may also try to read the address from the X Window System root window property

`_DBUS_SESSION_BUS_ADDRESS`.

The root window property must have type `STRING`.

The environment variable should have precedence over the root window property.

</para>

The address of the login session message bus is given in the

`DBUS_SESSION_BUS_ADDRESS` environment variable. If

`DBUS_SESSION_BUS_ADDRESS` is not set, or if it's set to the string

"autolaunch:", the system should use platform-specific methods of

locating a running D-Bus session server, or starting one if a running instance cannot be found. Note that this mechanism is not recommended

for attempting to determine if a daemon is running. It is inherently

racy to attempt to make this determination, since the bus daemon may

be started just before or just after the determination is made.

Therefore, it is recommended that applications do not try to make this

determination for their functionality purposes, and instead they

should attempt to start the server.</para>

<para>
At least the DBUS_SESSION_BUS_ADDRESS variable MUST be present
in this file.
</para>

<para>
Failure to open this file MUST be interpreted as absence of a running server. Therefore, the implementation MUST proceed to attempting to launch a new bus server if the file cannot be opened.
</para>

<para>
However, success in opening this file MUST NOT lead to the conclusion that the server is running. Thus, a failure to connect to the bus address obtained by the alternative method MUST NOT be considered a fatal error. If the connection cannot be established, the implementation MUST proceed to check the X selection settings or to start the server on its own.
</para>

<para>
If the implementation concludes that the D-Bus server is not running it MUST attempt to start a new server and it MUST also ensure that the daemon started as an effect of the "autolaunch" mechanism provides the lookup mechanisms described above, so subsequent calls can locate the newly started server. The concurrent implementation MUST also ensure that if two or more all other initiations happen, only one server remains running and and initiations are able to obtain the address of this server

connect to it. In other words, the implementation MUST ensure that the X selection is not present when it attempts to set it, without allowing another process to set the selection between the verification and the setting (e.g., by using XGrabServer / XungrabServer).

</para>
</sect4>
<sect4>
<title></title>
<para>
On Unix systems, the session bus should search for .service files in <literal>\$XDG_DATA_DIRS/dbus-1/services</literal> as defined by the <ulink url="http://standards.freedesktop.org/basedir-spec/basedir-spec-latest.html">XDG Base Directory Specification</ulink>.

Implementations may also search additional locations, which should be searched with lower priority than anything in XDG_DATA_HOME, XDG_DATA_DIRS or their respective defaults; for example, the reference implementation also looks in <literal>\${datadir}/dbus-1/services</literal> as set at compile time.

</para>
<para>
As described in the XDG Base Directory Specification, software packages should install their session .service files to their configured <literal>\${datadir}/dbus-1/services</literal>, where <literal>\${datadir}</literal> is as defined by the GNU coding standards. System administrators or users can arrange for these service files to be read by setting XDG_DATA_DIRS or by symlinking them into the default locations.

        <para>
            Before an application is able to send messages to other
            applications
            it must send the
    <literal>org.freedesktop.DBus.Hello</literal> message
            to the message bus to obtain a unique name. If an
            application without

```

a unique name tries to send a message to another application, or a message to the message bus itself that isn't the `<literal>org.freedesktop.DBus.Hello</literal>` message, it will be disconnected from the bus.

There is no corresponding "disconnect" request; if a client wishes to disconnect from the bus, it simply closes the socket (or other communication channel).

`<title><literal>org.freedesktop.DBus.ListNames</literal></title>`

<glossary><title>Glossary</title>
  <para>
    This glossary defines some of the terms used in this
specification.
  </para>

  <glossentry id="term-bus-name"><glossterm>Bus Name</glossterm>
    <glossdef>
      <para>
        The message bus maintains an association between names and
connections. (Normally, there's one connection per
application.) A
        bus name is simply an identifier used to locate connections.
For
        example, the hypothetical
<literal>com.yoyodyne.Screensaver</literal>
        name might be used to send a message to a screensaver from
Yoyodyne
        Corporation. An application is said to
<firstterm>own</firstterm> a
        name if the message bus has associated the application's
connection
        with the name. Names may also have <firstterm>queued
owners</firstterm> (see <xref linkend="term-queued-
owner"/>).
        The bus assigns a unique name to each connection,
        see <xref linkend="term-unique-name"/>. Other names
        can be thought of as "well-known names" and are
        used to find applications that offer specific
functionality.
      </para>

      <para>
        See <xref linkend="message-protocol-names-bus"/> for details
of

  <glossdef>
    <para>
      Each application contains <firstterm>objects</firstterm>,
which have
      <firstterm>interfaces</firstterm> and
      <firstterm>methods</firstterm>. Objects are referred to by a
name,
      called a <firstterm>path</firstterm>.
    </para>
  </glossdef>

```

</glossentry>

<glossentry id="one-to-one"><glossterm>One-to-One</glossterm>

<glossdef>

<para>

An application talking directly to another application, without going through a message bus. One-to-one connections may be "peer to peer" or "client to server." The D-Bus protocol has no concept of client vs. server after a connection has authenticated; the flow of messages is symmetrical (full duplex).

</para>

</glossdef>

</glossentry>

<glossentry id="term-path"><glossterm>Path</glossterm>

<glossdef>

<para>

Object references (object names) in D-Bus are organized into a filesystem-style hierarchy, so each object is named by a path. As in LDAP, there's no difference between "files" and "directories"; a path can refer to an object, while still having child objects below it.

</para>

</glossdef>

</glossentry>

<glossentry id="term-queued-owner"><glossterm>Queued Name Owner</glossterm>

<glossdef>

<para>

Each bus name has a primary owner; messages sent to the name go to the primary owner. However, certain names also maintain a queue of secondary owners "waiting in the wings." If the primary owner releases the name, then the first secondary owner in the queue automatically becomes the new owner of the name.

</para>

</glossdef>

</glossentry>

<glossentry id="term-service"><glossterm>Service</glossterm>

<glossdef>

```
<para>
  A service is an executable that can be launched by the bus
daemon.
  Services normally guarantee some particular features, for
example they
  may guarantee that they will request a specific name such as
  "org.freedesktop.Screensaver", have a singleton object
  "/org/freedesktop/Application", and that object will
implement the
  interface "org.freedesktop.ScreensaverControl".
</para>
</glossdef>
</glossentry>
```

```
<glossentry id="term-service-description-files"><glossterm>Service
Description Files</glossterm>
<glossdef>
<para>
  ".service files" tell the bus about service applications
that can be
  launched (see <xref linkend="term-service"/>). Most
importantly they
  provide a mapping from bus names to services that will
request those
  names when they start up.
</para>
</glossdef>

/**
* @defgroup DBusString DBusString class
* @ingroup DBusInternals

```

```

* @brief DBusString data structure for safer string handling
*
* Types and functions related to DBusString. DBusString is intended
* to be a string class that makes it hard to mess up security issues
* (and just in general harder to write buggy code). It should be
* used (or extended and then used) rather than the libc stuff in
* string.h. The string class is a bit inconvenient at spots because
* it handles out-of-memory failures and tries to be extra-robust.
*
* A DBusString has a maximum length set at initialization time; this
* can be used to ensure that a buffer doesn't get too big. The
* _dbus_string_lengthen() method checks for overflow, and for max
* length being exceeded.
*
* Try to avoid conversion to a plain C string, i.e. add methods on
* the string object instead, only convert to C string when passing
* things out to the public API. In particular, no sprintf, strcpy,
* strcat, any of that should be used. The GString feature of
* accepting negative numbers for "length of string" is also absent,
* because it could keep us from detecting bogus huge lengths. i.e. if
* we passed in some bogus huge length it would be taken to mean
* "current length of string" instead of "broken crack"
*
* @todo #DBusString needs a lot of cleaning up; some of the
* API is no longer used, and the API is pretty inconsistent.
* In particular all the "append" APIs, especially those involving
* alignment but probably lots of them, are no longer used by the
* marshaling code which always does "inserts" now.

class="titlepage"><div><div><h3 class="title"><a name="importance-of-
testing"></a>The importance of testing</h3></div></div></div><p>
    As with any big library or program, testing is important. It
    can help find bugs and regressions and make the code better
    overall.
    </p><p>
    D-Bus is a large and complex piece of software (about 25,000
    lines of code for the client library, and 2,500 lines of code
    for the bus daemon) and it's therefore important to try to
make sure
    that all parts of the software is functioning correctly.
    </p><p>
    D-Bus can be built with support for testing by passing
    <code class="literal">--enable-tests</code>. to the configure
script. It
    is recommended that production systems build without testing
    since that reduces the D-Bus client library size.
    </p></div></div><div class="sect1" title="Testing the D-Bus
client library"><div class="titlepage"><div><div><h2 class="title"
style="clear: both"><a name="client-library"></a>Testing the D-Bus
client library</h2></div></div></div><p>
    The tests for the client library consist of the dbus-test
    program which is a unit test for all aspects of the client
    library. Whenever a bug in the client library is found and
    fixed, a test is added to make sure that the bug won't occur
again.
    </p><div class="sect2" title="Data Structures"><div
class="titlepage"><div><div><h3 class="title"><a name="data-
structures"></a>Data Structures</h3></div></div></div><p>
    The D-Bus client library consists of some data structures that
    are used internally; a linked list class, a hashtable class and
    a string class. All aspects of those are tested by dbus-test.
    </p></div><div class="sect2" title="Message loader"><div
class="titlepage"><div><div><h3 class="title"><a name="message-
loader"></a>Message loader</h3></div></div></div><p>
    The message loader is the part of D-Bus that takes messages in
    raw character form and parses them, turning them into
DBusMessages.
    </p><p>
    This is one of the parts of D-Bus that
```

must be absolutely bug-free and

robust. The message loader should be able to handle invalid and incomplete messages without crashing. Not doing so is a serious issue and can easily result in D-Bus being exploitable to DoS attacks.

</p><p>

To solve these problems, there is a testing feature called the Message Builder. The message builder can take a serialized message in string-form and convert it into a raw character string which can then be loaded by the message loader.

</p><div class="figure"><p class="title">Figure 1. Example of a message in string form</p><div class="figure-contents"><pre class="programlisting">
Standard org.freedesktop.DBus.Hello message

```
VALID_HEADER  
FIELD_NAME name  
TYPE STRING  
STRING 'org.freedesktop.DBus.Hello'  
FIELD_NAME srvc  
TYPE STRING  
STRING 'org.freedesktop.DBus'  
ALIGN 8  
END_LENGTH Header  
START_LENGTH Body  
END_LENGTH Body
```

</pre></div></div><br class="figure-break"><p>

The file format of messages in string form is documented in the D-Bus Reference Manual.

</p><p>

The message test part of dbus-test is using the message builder to build different kinds of messages, both valid, invalid, and invalid ones, to make sure that the loader won't crash or leak memory of any of those, and that the loader knows if a message is valid or not.

</p><p>

There is also a test program called `break-loader` that loads a message

in

string-form into raw character form using the message builder. It then randomly changes the message, it can for example replace single bytes of data or modify the length of the message. This is to simulate network errors. The break-loader program saves all the messages leading to errors so it can easily be run for a long period of time.

</p></div><div class="sect2" title="Authentication"><div class="titlepage"><div><div><h3 class="title">Authentication</h3></div></div></div><p>

For testing authentication, there is a testing feature that can read authentication sequences from a file and play them back to a dummy server and client to make sure that

authentication is working according to the specification.

[Figure 2. Example of an authentication script](#)

```

## this tests a successful auth of type EXTERNAL

SERVER
SEND 'AUTH EXTERNAL USERNAME_HEX'
EXPECT_COMMAND OK
EXPECT_STATE WAITING_FOR_INPUT
SEND 'BEGIN'
EXPECT_STATE AUTHENTICATED

```

Testing the D-Bus bus daemon

Testing the D-Bus bus daemon

Since the D-Bus bus daemon is using the D-Bus client library it will benefit from all tests done on the client library, but there is still the issue of testing client-server communication. This is more complicated since it it may require another process running.

The debug transport

The debug transport

In D-Bus, a **transport** is a class that handles sending and receiving raw data over a certain medium. The transport that is used most in D-Bus is the UNIX transport with sends and recevies data over a UNIX socket. A transport that tunnels data through X11 client messages is also under development.

The D-Bus debug transport is a specialized transport that works in-process. This means that a client and server that exists in the same process can talk to eachother without using a socket.

The bus-test program

The bus-test program is a program that is used to test various parts of the D-Bus bus daemon; robustness and that it conforms to the specifications.

The test program has the necessary code from the bus daemon linked in, and it uses the debug transport for communication. This means that the bus daemon code can be tested without the real bus actually running, which makes testing easier.

The bus-test program should test all major features of the

```

    bus, such as service registration, notification when things
    occurs and message matching.
  </p></div></div><div class="sect1" title="Other tests"><div
class="titlepage"><div><div><h2 class="title" style="clear: both"><a
name="other-tests"></a>Other tests</h2></div></div></div><div
class="sect2" title="Out-Of-Memory robustness"><div
class="titlepage"><div><div><h3 class="title"><a name="oom-
robustness"></a>Out-Of-Memory robustness</h3></div></div></div><p>
    Since D-Bus should be able to be used in embedded devices, and
    also as a system service, it should be able to cope with
    low-memory situations without exiting or crashing.
  </p><p>
    In practice, this means that both the client and server code
    must be able to handle dbus_malloc returning NULL.
  </p><p>
    To test this, two environment variables
    exist. <code class="literal">DBUS_MALLOC_FAIL_NTH</code> will
make every
    nth call to dbus_malloc return NULL, and
    <code class="literal">DBUS_MALLOC_FAIL_GREATER_THAN</code>
will make any
    dbus_malloc call with a request for more than the specified
    number of bytes fail.
  </p></div><div class="sect2" title="Memory leaks and code
robustness"><div class="titlepage"><div><div><h3 class="title"><a
name="leaks-and-other-stuff"></a>Memory leaks and code
robustness</h3></div></div></div><p>
    Naturally there are some things that tests can't be written
    for, for example things like memory leaks and out-of-bounds
    memory reading or writing.
  </p><p>
    Luckily there exists good tools for catching such errors. One
    free good tool is <a class="ulink" href="http://devel-
home.kde.org/~sewardj/" target="_top">Valgrind</a>, which runs the
    program in a
    virtual CPU which makes catching errors easy. All test
    programs can be run under Valgrind,
  </p></div></div></div></body></html>

</para>
<para>
    The D-Bus debug transport is a specialized transport that
    works in-process. This means that a client and server that
    exists in the same process can talk to eachother without using
    a socket.
</para>
</sect2>
<sect2 id="bus-test">
    <title>The bus-test program</title>
    <para>
        The bus-test program is a program that is used to test various
        parts of the D-Bus bus daemon; robustness and that it conforms
        to the specifications.
    </para>
    <para>
        The test program has the necessary code from the bus daemon
        linked in, and it uses the debug transport for
        communication. This means that the bus daemon code can be
        tested without the real bus actually running, which makes
        testing easier.
    </para>
    <para>
        The bus-test program should test all major features of the
        bus, such as service registration, notification when things
        occurs and message matching.
    </para>
</sect2>
</sect1>
<sect1 id="other-tests">
    <title>Other tests</title>

    <sect2 id="oom-robustness">
        <title>Out-Of-Memory robustness</title>
        <para>
            Since D-Bus should be able to be used in embedded devices, and
            also as a system service, it should be able to cope with
            low-memory situations without exiting or crashing.
        </para>
        <para>
            In practice, this means that both the client and server code
            must be able to handle dbus_malloc returning NULL.
        </para>
        <para>
            To test this, two environment variables
            exist. <literal>DBUS_MALLOC_FAIL_NTH</literal> will make every
            nth call to dbus_malloc return NULL, and
            <literal>DBUS_MALLOC_FAIL_GREATER_THAN</literal> will make any
            dbus_malloc call with a request for more than the specified
```

```

    number of bytes fail.
  </para>
</sect2>

<sect2 id="leaks-and-other-stuff">
  <title>Memory leaks and code robustness</title>
  <para>
    Naturally there are some things that tests can't be written
    for, for example things like memory leaks and out-of-bounds
    memory reading or writing.
  </para>
  <para>
    Luckily there exists good tools for catching such errors. One
    free good tool is <ulink url="http://devel-
    home.kde.org/~sewardj/">Valgrind</ulink>, which runs the program in a
    virtual CPU which makes catching errors easy. All test
    programs can be run under Valgrind,
  </para>

Tutorial Work In Progress

Tutorial Work In Progress

This tutorial is not complete; it probably contains some useful information, but

also has plenty of gaps. Right now, you'll also need to refer to the D-Bus specification,

Doxygen reference documentation, and look at some examples of how other apps use D-Bus.

</p><p>

Enhancing the tutorial is definitely encouraged - send your patches or suggestions to the

mailing list. If you create a D-Bus binding, please add a section to the tutorial for your

binding, if only a short section with a couple of examples.

</p></div><div class="sect1" title="What is D-Bus?"><div class="titlepage"><div><div><h2 class="title" style="clear: both">What is D-Bus?</h2></div></div></div><p>

D-Bus is a system for <em class="firstterm">interprocess communication

(IPC). Architecturally, it has several layers:

</p><div class="itemizedlist"><ul class="itemizedlist" type="disc"><li class="listitem"><p>

A library, <em class="firstterm">libdbus, that allows two

applications to connect to each other and exchange messages.

</p><li class="listitem"><p>

A <em class="firstterm">message bus daemon executable, built on

libdbus, that multiple applications can connect to. The daemon can

route messages from one application to zero or more other applications.

</p><li class="listitem"><p>

<em class="firstterm">Wrapper libraries or <em class="firstterm">bindings

based on particular application frameworks. For example, libdbus-glib and

libdbus-qt. There are also bindings to languages such as Python. These wrapper libraries are the API most people should use,

as they simplify the details of D-Bus programming. libdbus is

intended to be a low-level backend for the higher level bindings.

Much of the libdbus API is only useful for binding implementation.

</p></div><p>

</p><p>

libdbus only supports one-to-one connections, just like a raw network

socket. However, rather than sending byte streams over the connection, you

send <em class="firstterm">messages. Messages have a header identifying

the kind of message, and a body containing a data payload. libdbus also

abstracts the exact transport used (sockets vs. whatever else),
and handles details such as authentication.

</p><p>

The message bus daemon forms the hub of a wheel. Each spoke of
the wheel

is a one-to-one connection to an application using libdbus. An
application sends a message to the bus daemon over its spoke,
and the bus

daemon forwards the message to other connected applications as
appropriate. Think of the daemon as a router.

</p><p>

The bus daemon has multiple instances on a typical computer.

The

first instance is a machine-global singleton, that is, a system
daemon

similar to sendmail or Apache. This instance has heavy security
restrictions on what messages it will accept, and is used for
systemwide

communication. The other instances are created one per user
login session.

These instances allow applications in the user's session to
communicate

with one another.

</p><p>

The systemwide and per-user daemons are separate. Normal
within-session

IPC does not involve the systemwide message bus process and vice
versa.

</p><div class="sect2" title="D-Bus applications"><div
class="titlepage"><div><div><h3 class="title">D-Bus
applications</h3></div></div></div><p>

There are many, many technologies in the world that have
"Inter-process

communication" or "networking" in their stated purpose: CORBA, <a

and probably hundreds more.

Each of these is tailored for particular kinds of application.

D-Bus is designed for two specific cases:

</p><div class="itemizedlist"><ul class="itemizedlist"
type="disc"><li class="listitem"><p>

desktop
a whole,
components

Communication between desktop applications in the same session; to allow integration of the desktop session as a whole, and address issues of process lifecycle (when do desktop start and stop running).

operating system,
kernel

Communication between the desktop session and the where the operating system would typically include the and any system daemons or processes.

For the within-desktop-session use case, the GNOME and KDE desktops have significant previous experience with different IPC solutions such as CORBA and DCOP. D-Bus is built on that experience and carefully tailored to meet the needs of these desktop projects in particular. D-Bus may or may not be appropriate for other applications; the FAQ has some comparisons to other IPC systems.

The problem solved by the systemwide or communication-with-the-OS case is explained well by the following text from the Linux Hotplug project:

A gap in current Linux support is that policies with any sort of dynamic "interact with user" component aren't currently supported. For example, that's often needed the first time a network adapter or printer is connected, and to determine appropriate places to mount disk drives. It would seem that such actions could be supported for any case where a responsible human can be identified: single user workstations, or any system which is remotely administered.

This is a classic "remote sysadmin" problem, where in this case hotplugging needs to deliver an event from one security domain (operating system kernel, in this case) to another (desktop for logged-in user, or remote sysadmin). Any effective response must go

the other way: the remote domain taking some action that lets the kernel expose the desired device capabilities. (The action can often be taken asynchronously, for example letting new hardware be idle until a meeting finishes.) At this writing, Linux doesn't have widely adopted solutions to such problems. However, the new D-Bus work may begin to solve that problem.

D-Bus may happen to be useful for purposes other than the one it was designed for. Its general properties that distinguish it from other forms of IPC are:

- Binary protocol designed to be used asynchronously (similar in spirit to the X Window System protocol).
- Stateful, reliable connections held open over time.
- The message bus is a daemon, not a "swarm" or distributed architecture.
- Many implementation and deployment issues are specified rather than left ambiguous/configurable/pluggable.
- Semantics are similar to the existing DCOP system, allowing KDE to adopt it more easily.
- Security features to support the systemwide mode of the message bus.

Concepts

Concepts

Some basic concepts apply no matter what application framework you're using to write a D-Bus application. The exact code you write will be different for GLib vs. Qt vs. Python applications, however.

Here is a diagram ([png](diagram.png) [svg](diagram.svg)) that may help you visualize the concepts that follow.

</p><div class="sect2" title="Native Objects and Object Paths"><div class="titlepage"><div><div><h3 class="title">Native Objects and Object Paths</h3></div></div></div><p>

Your programming framework probably defines what an "object" is like;

usually with a base class. For example: java.lang.Object, GObject, QObject, python's base Object, or whatever. Let's call this a <em class="firsttterm">native object.

</p><p>

The low-level D-Bus protocol, and corresponding libdbus API, does not care about native objects.

However, it provides a concept called an

<em class="firsttterm">object path. The idea of an object path is that

higher-level bindings can name native object instances, and allow remote applications to refer to them.

</p><p>

The object path

looks like a filesystem path, for example an object could be named <code

class="literal">/org/kde/kspread/sheets/3/cells/4/5</code>.

Human-readable paths are nice, but you are free to create an object named <code

class="literal">/com/mycompany/c5yo817y0c1y1c5b</code>

if it makes sense for your application.

</p><p>

Namespacing object paths is smart, by starting them with the components

of a domain name you own (e.g. <code

class="literal">/org/kde/</code>). This keeps different code modules in the same process from stepping on one another's toes.

</p></div><div class="sect2" title="Methods and Signals"><div

class="titlepage"><div><div><h3 class="title">Methods and Signals</h3></div></div></div><p>

Each object has <em class="firsttterm">members; the two kinds of member

are <em class="firsttterm">methods and

<em class="firsttterm">signals. Methods are operations that can be

invoked on an object, with optional input (aka arguments or "in

parameters") and output (aka return values or "out parameters").

Signals are broadcasts from the object to any interested observers

of the object; signals may contain a data payload.

</p><p>

Both methods and signals are referred to by name, such as

"Frobate" or "OnClicked".

[Interfaces](#)

Each object supports one or more `interfaces`.

Think of an interface as a named group of methods and signals, just as it is in GLib or Qt or Java. Interfaces define the `type` of an object instance.

DBus identifies interfaces with a simple namespaced string, something like `org.freedesktop.Introspectable`.

Most bindings will map these interface names directly to the appropriate programming language construct, for example to Java interfaces or C++ pure virtual classes.

[Proxies](#)

A `proxy object` is a convenient native object created to represent a remote object in another process. The low-level DBus API involves manually creating a method call message, sending it, then manually receiving and processing the method reply message. Higher-level bindings provide proxies as an alternative.

Proxies look like a normal native object; but when you invoke a method on the proxy object, the binding converts it into a DBus method call message, waits for the reply message, unpacks the return value, and returns it from the native method..

In pseudocode, programming without proxies might look like this:

```
Message message = new Message("/remote/object/path",
"MethodName", arg1, arg2);
Connection connection = getBusConnection();
connection.send(message);
Message reply = connection.waitForReply(message);
if (reply.isError()) {

} else {
    Object returnValue = reply.getReturnValue();
}
```

Programming with proxies might look like this:

```
Message message = new Message("/remote/object/path",
```

```
Proxy proxy = new Proxy(getBusConnection(),
"/remote/object/path");
Object returnValue = proxy.MethodName(arg1, arg2);
</pre><p>
```

</p></div><div class="sect2" title="Bus Names"><div class="titlepage"><div><div><h3 class="title">Bus Names</h3></div></div></div><p>

When each application connects to the bus daemon, the daemon immediately

assigns it a name, called the <em class="firstterm">unique connection name.

A unique name begins with a ':' (colon) character. These names are never

reused during the lifetime of the bus daemon - that is, you know

a given name will always refer to the same application.

An example of a unique name might be

<code class="literal">:34-907</code>. The numbers after the colon have

no meaning other than their uniqueness.

</p><p>

When a name is mapped

to a particular application's connection, that application is said to

<em class="firstterm">own that name.

</p><p>

Applications may ask to own additional <em class="firstterm">well-known

names. For example, you could write a specification to define a name called <code

class="literal">com.mycompany.TextEditor</code>.

Your definition could specify that to own this name, an application

should have an object at the path

<code class="literal">/com/mycompany/TextFileManager</code> supporting the

interface <code

class="literal">org.freedesktop.FileHandler</code>.

</p><p>

Applications could then send messages to this bus name, object, and interface to execute method calls.

</p><p>

You could think of the unique names as IP addresses, and the well-known names as domain names. So

<code class="literal">com.mycompany.TextEditor</code> might map to something like

<code class="literal">:34-907</code> just as <code class="literal">mycompany.com</code> maps

to something like <code class="literal">192.168.0.5</code>.

</p><p>

Names have a second important use, other than routing messages. They

are used to track lifecycle. When an application exits (or crashes), its connection to the message bus will be closed by the operating system kernel. The message bus then sends out notification messages telling remaining applications that the application's names have lost their owner. By tracking these notifications, your application can reliably monitor the lifetime of other applications.

`</p><p>`
Bus names can also be used to coordinate single-instance applications. If you want to be sure only one `<code class="literal">com.mycompany.TextEditor</code>` application is running for example, have the text editor application exit if the bus name already has an owner.

`</p></div><div class="sect2" title="Addresses"><div class="titlepage"><div><div><h3 class="title">Addresses</h3></div></div></div><p>`
Applications using D-Bus are either servers or clients. A server listens for incoming connections; a client connects to a server. Once the connection is established, it is a symmetric flow of messages; the client-server distinction only matters when setting up the connection.

`</p><p>`
If you're using the bus daemon, as you probably are, your application will be a client of the bus daemon. That is, the bus daemon listens for connections and your application initiates a connection to the bus daemon.

`</p><p>`
A D-Bus `<em class="firsttterm">address` specifies where a server will listen, and where a client will connect. For example, the address `<code class="literal">unix:path=/tmp/abcdef</code>` specifies that the server will listen on a UNIX domain socket at the path `<code class="literal">/tmp/abcdef</code>` and the client will connect to that socket. An address can also specify TCP/IP sockets, or any other

transport defined in future iterations of the D-Bus specification.

</p><p>

When using D-Bus with a message bus daemon, libdbus automatically discovers the address of the per-session bus

daemon by reading an environment variable. It discovers the systemwide bus daemon by checking a well-known UNIX domain socket path

(though you can override this address with an environment variable).

</p><p>

If you're using D-Bus without a bus daemon, it's up to you to define which application will be the server and which will be the client, and specify a mechanism for them to agree on the server's address. This is an unusual case.

</p></div><div class="sect2" title="Big Conceptual Picture"><div class="titlepage"><div><div><h3 class="title">Big Conceptual Picture</h3></div></div></div><p>

Pulling all these concepts together, to specify a particular method call on a particular object instance, a number of nested components have to be named:

</p><pre class="programlisting">

```
Address -&gt; [Bus Name] -&gt; Path -&gt; Interface -&gt;
```

Method

</pre><p>

The bus name is in brackets to indicate that it's optional -- you only

provide a name to route the method call to the right application

when using the bus daemon. If you have a direct connection to another

application, bus names aren't used; there's no bus daemon.

</p><p>

The interface is also optional, primarily for historical reasons; DCOP does not require specifying the interface, instead simply forbidding duplicate method names on the same object instance. D-Bus will thus let you omit the interface, but if your method name is ambiguous it is undefined which method will be invoked.

</p></div><div class="sect2" title="Messages - Behind the Scenes"><div class="titlepage"><div><div><h3 class="title">Messages - Behind the Scenes</h3></div></div></div><p>

D-Bus works by sending messages between processes. If you're using

a sufficiently high-level binding, you may never work with messages directly.

</p><p>

There are 4 message types:

</p><div class="itemizedlist"><ul class="itemizedlist" type="disc"><li class="listitem"><p>

Method call messages ask to invoke a method on an object.

</p><li class="listitem"><p>

Method return messages return the results of invoking a method.

</p><li class="listitem"><p>

Error messages return an exception caused by invoking a method.

</p><li class="listitem"><p>

Signal messages are notifications that a given signal has been emitted (that an event has occurred).

You could also think of these as "event" messages.

</p></div><p>

</p><p>

A method call maps very simply to messages: you send a method call

message, and receive either a method return message or an error message

in reply.

</p><p>

Each message has a <em class="firsttterm">header, including <em class="firsttterm">fields,

and a <em class="firsttterm">body, including <em class="firsttterm">arguments. You can think

of the header as the routing information for the message, and the body as the payload.

Header fields might include the sender bus name, destination bus name, method or signal name,

and so forth. One of the header fields is a <em class="firsttterm">type signature describing the

values found in the body. For example, the letter "i" means "32-bit integer" so the signature

"ii" means the payload has two 32-bit integers.

</p></div><div class="sect2" title="Calling a Method - Behind the Scenes"><div class="titlepage"><div><div><h3 class="title">Calling a Method - Behind the Scenes</h3></div></div></div><p>

A method call in DBus consists of two messages; a method call message sent from process A to process B,

and a matching method reply message sent from process B to process A. Both the call and the reply messages

are routed through the bus daemon. The caller includes a different serial number in each call message, and the

reply message includes this number to allow the caller to match replies to calls.

</p><p>

The call message will contain any arguments to the method.

The reply message may indicate an error, or may contain data returned by the method.

</p><p>

A method invocation in DBus happens as follows:

```
</p><div class="itemizedlist"><ul class="itemizedlist"
type="disc"><li class="listitem"><p>
    The language binding may provide a proxy, such that
    invoking a method on
        an in-process object invokes a method on a remote object
    in another process. If so, the
        application calls a method on the proxy, and the proxy
        constructs a method call message to send to the remote
    process.
</p></li><li class="listitem"><p>
    For more low-level APIs, the application may construct a
    method call message itself, without
        using a proxy.
</p></li><li class="listitem"><p>
    In either case, the method call message contains: a bus
    name belonging to the remote process; the name of the method;
        the arguments to the method; an object path inside the
    remote process; and optionally the name of the
        interface that specifies the method.
</p></li><li class="listitem"><p>
    The method call message is sent to the bus daemon.
</p></li><li class="listitem"><p>
    The bus daemon looks at the destination bus name. If a
    process owns that name,
        the bus daemon forwards the method call to that process.
    Otherwise, the bus daemon
        creates an error message and sends it back as the reply
    to the method call message.
</p></li><li class="listitem"><p>
    The receiving process unpacks the method call message.
    In a simple low-level API situation, it
        may immediately run the method and send a method reply
    message to the bus daemon.
        When using a high-level binding API, the binding might
    examine the object path, interface,
        and method name, and convert the method call message
    into an invocation of a method on
        a native object (GObject, java.lang.Object, GObject,
    etc.), then convert the return
        value from the native method into a method reply
    message.
</p></li><li class="listitem"><p>
    The bus daemon receives the method reply message and
    sends it to the process that
        made the method call.
</p></li><li class="listitem"><p>
    The process that made the method call looks at the
    method reply and makes use of any
        return values included in the reply. The reply may also
    indicate that an error occurred.
        When using a binding, the method reply message may be
    converted into the return value of
```

of a proxy method, or into an exception.

The bus daemon never reorders messages. That is, if you send two method call messages to the same recipient, they will be received in the order they were sent. The recipient is not required to reply to the calls in order, however; for example, it may process each method call in a separate thread, and return reply messages in an undefined order depending on when the threads complete. Method calls have a unique serial number used by the method caller to match reply messages to call messages.

A signal in DBus consists of a single message, sent by one process to any number of other processes.

That is, a signal is a unidirectional broadcast. The signal may contain arguments (a data payload), but

because it is a broadcast, it never has a "return value." Contrast this with a method call

(see [the section called "Calling a Method - Behind the Scenes"](#) where the method call message has a matching method reply message.

The emitter (aka sender) of a signal has no knowledge of the signal recipients. Recipients register

with the bus daemon to receive signals based on "match rules" - these rules would typically include the sender and

the signal name. The bus daemon sends each signal only to recipients who have expressed interest in that signal.

A signal in DBus happens as follows:

- A signal message is created and sent to the bus daemon.

- When using the low-level API this may be

- done manually, with certain bindings it may be done for you by the binding when a native object emits a native signal or event.

-

- The signal message contains the name of the interface that specifies the signal;

- the name of the signal; the bus name of the process sending the signal; and

- any arguments

-

Any process on the message bus can register "match rules" indicating which signals it is interested in. The bus has a list of registered match rules.

The bus daemon examines the signal and determines which processes are interested in it.

It sends the signal message to these processes.

Each process receiving the signal decides what to do with it; if using a binding, the binding may choose to emit a native signal on a proxy object. If using the low-level API, the process may just look at the signal sender and name and decide what to do based on that.

[Introspection](#)

D-Bus objects may support the interface `org.freedesktop.DBus.Introspectable`.

This interface has one method `Introspect` which takes no arguments and returns an XML string. The XML string describes the interfaces, methods, and signals of the object.

See the D-Bus specification for more details on this introspection format.

[GLib API: Using Remote Objects](#)

GLib API: Using Remote Objects

The GLib binding is defined in the header file `<dbus/dbus-glib.h>`.

[D-Bus - GLib type mappings](#)

D-Bus - GLib type mappings

The heart of the GLib bindings for D-Bus is the mapping it provides between D-Bus "type signatures" and GLib types (`GType`). The D-Bus type system is composed of

a number of "basic" types, along with several "container" types.

[Basic type mappings](#)

Basic type mappings

Below is a list of the basic types, along with their associated mapping to a `GType`.

D-Bus basic type	GType	Free function	Notes
	<code>BYTE</code>		

<code>G_TYPE_UCHAR</code>			
<code>BOOLEAN</code>			
<code>G_TYPE_BOOLEAN</code>			
<code>INT16</code>			
<code>G_TYPE_INT</code>			Will be changed to a <code>G_TYPE_INT16</code> once GLib has it
<code>UINT16</code>			
<code>G_TYPE_UINT</code>			Will be changed to a <code>G_TYPE_UINT16</code> once GLib has it
<code>INT32</code>			
<code>G_TYPE_INT</code>			Will be changed to a <code>G_TYPE_INT32</code> once GLib has it
<code>UINT32</code>			
<code>G_TYPE_UINT</code>			Will be changed to a <code>G_TYPE_UINT32</code> once GLib has it
<code>INT64</code>			
<code>G_TYPE_GINT64</code>			
<code>UINT64</code>			
<code>G_TYPE_GUINT64</code>			
<code>DOUBLE</code>			
<code>G_TYPE_DOUBLE</code>			
<code>STRING</code>			
<code>G_TYPE_STRING</code>			
<code>g_free</code>			
<code>OBJECT_PATH</code>			
<code>DBUS_TYPE_G_PROXY</code>			
<code>g_object_unref</code>			The returned proxy does not have an interface set; use <code>dbus_g_proxy_set_interface</code> to invoke methods

As you can see, the basic mapping is fairly straightforward.

</p></div><div class="sect3" title="Container type mappings"><div class="titlepage"><div><div><h4 class="title">Container type mappings</h4></div></div></div><p>

The D-Bus type system also has a number of "container" types, such as `DBUS_TYPE_ARRAY` and `DBUS_TYPE_STRUCT`. The D-Bus type system

is fully recursive, so one can for example have an array of array of strings (i.e. type signature `aas`).

</p><p>

However, not all of these types are in common use; for example, at the time of this writing the author knows of no one using `DBUS_TYPE_STRUCT`, or a `DBUS_TYPE_ARRAY` containing any non-basic

type. The approach the GLib bindings take is pragmatic; try to map the most common types in the most obvious way, and let using less common and more complex types be less "natural".

</p><p>

First, D-Bus type signatures which have an "obvious" corresponding built-in GLib type are mapped using that type:

D-Bus type	Description	GType	C typedef	Free function	Notes
<code>as</code>	Array of strings	<code>G_TYPE_STRV</code>	<code>char **</code>	<code>g_strfreev</code>	
<code>v</code>	Generic value container	<code>G_TYPE_VALUE</code>	<code>GValue *</code>	<code>g_value_unset</code>	The calling conventions for values expect that method callers have allocated return values; see below.

The next most common recursive type signatures are arrays of basic values. The most obvious mapping for arrays of basic types is a `GArray`. Now, GLib does not

provide a builtin `GType` for `GArray`. However, we actually need more than that - we need a "parameterized" type which includes the contained type. Why we need this we will see below.

The approach taken is to create these types in the D-Bus GLib bindings; however, there is nothing D-Bus specific about them. In the future, we hope to include such "fundamental" types in GLib

itself.

D-Bus type	Description	GType	C typedef	Free function	Notes
<code>ay</code>	Array of bytes	<code>DBUS_TYPE_G_BYTE_ARRAY</code>	<code>GArray *</code>	<code>g_array_free</code>	
<code>au</code>	Array of uint	<code>DBUS_TYPE_G_UINT_ARRAY</code>	<code>GArray *</code>	<code>g_array_free</code>	
<code>ai</code>	Array of int	<code>DBUS_TYPE_G_INT_ARRAY</code>	<code>GArray *</code>	<code>g_array_free</code>	

```

class="literal">ax</code></td><td>Array of int64</td><td><code
class="literal">DBUS_TYPE_G_INT64_ARRAY</code></td><td><code
class="literal">GArray
*</code></td><td>g_array_free</td><td> </td></tr><tr><td><code
class="literal">at</code></td><td>Array of uint64</td><td><code
class="literal">DBUS_TYPE_G_UINT64_ARRAY</code></td><td><code
class="literal">GArray
*</code></td><td>g_array_free</td><td> </td></tr><tr><td><code
class="literal">ad</code></td><td>Array of double</td><td><code
class="literal">DBUS_TYPE_G_DOUBLE_ARRAY</code></td><td><code
class="literal">GArray
*</code></td><td>g_array_free</td><td> </td></tr><tr><td><code
class="literal">ab</code></td><td>Array of boolean</td><td><code
class="literal">DBUS_TYPE_G_BOOLEAN_ARRAY</code></td><td><code
class="literal">GArray
*</code></td><td>g_array_free</td><td> </td></tr></tbody></table></div
><p>

```

</p><p>

D-Bus also includes a special type `DBUS_TYPE_DICT_ENTRY` which is only valid in arrays. It's intended to be mapped to a "dictionary" type by bindings. The obvious GLib mapping here is `GHashTable`. Again, however, there is no builtin `GType` for a `GHashTable`. Moreover, just like for arrays, we need a parameterized type so that the bindings can communicate which types are contained in the hash table.

</p><p>

At present, only strings are supported. Work is in progress to include more types.

```

</p><div class="informaltable"><table
border="1"><colgroup><col><col><col><col><col><col></colgroup><thead><
tr><th>D-Bus type
signature</th><th>Description</th><th>GType</th><th>C
typedef</th><th>Free
function</th><th>Notes</th></tr></thead><tbody><tr><td><code
class="literal">a{ss}</code></td><td>Dictionary mapping strings to
strings</td><td><code
class="literal">DBUS_TYPE_G_STRING_STRING_HASHTABLE</code></td><td><co
de class="literal">GHashTable
*</code></td><td>g_hash_table_destroy</td><td> </td></tr></tbody></tab
le></div><p>

```

```

</p></div><div class="sect3" title="Arbitrarily recursive type
mappings"><div class="titlepage"><div><div><h4 class="title"><a
name="glib-generic-typemappings"></a>Arbitrarily recursive type
mappings</h4></div></div></div><p>

```

Finally, it is possible users will want to write or invoke D-Bus methods which have arbitrarily complex type signatures not directly supported by these bindings. For this case, we have a

`DBusGValue` which acts as a kind of special

variant value which may be iterated over manually. The

`GType` associated is

`DBUS_TYPE_G_VALUE`.

TODO insert usage of `DBUS_TYPE_G_VALUE` here.

`<div class="sect2" title="A sample program"><div class="titlepage"><div><div><h3 class="title">A sample program</h3></div></div></div><p>Here is a D-Bus program using the GLib bindings.`

`</p><pre class="programlisting">`

                        error-&gt;message);
        else
            g_printerr ("Error: %s\n", error-&gt;message);
        g_error_free (error);
        exit (1);
    }

    /* Print the results */

    g_print ("Names on the message bus:\n");

    for (name_list_ptr = name_list; *name_list_ptr; name_list_ptr++)
        {
            g_print (" %s\n", *name_list_ptr);
        }
    g_strfreev (name_list);

    g_object_unref (proxy);

    return 0;
}

```

</pre><p>

</p></div><div class="sect2" title="Program initalization"><div class="titlepage"><div><div><h3 class="title">Program initalization</h3></div></div></div><p>

A connection to the bus is acquired using `dbus_g_bus_get`. Next, a proxy is created for the object `"/org/freedesktop/DBus"` with interface `org.freedesktop.DBus` on the service `org.freedesktop.DBus`. This is a proxy for the message bus itself.

</p></div><div class="sect2" title="Understanding method invocation"><div class="titlepage"><div><div><h3 class="title">Understanding method invocation</h3></div></div></div><p>

You have a number of choices for method invocation. First, as used above, `dbus_g_proxy_call` sends

a

method call to the remote object, and blocks until a reply is recieved. The outgoing arguments are specified in the varargs array, terminated with

class="literal">G_TYPE_INVALID</code>.

Next, pointers to return values are specified, followed again by `G_TYPE_INVALID`.

</p><p>

To invoke a method asynchronously, use

`dbus_g_proxy_begin_call`. This returns a

```

    <code class="literal">DBusGPendingCall</code> object; you may
then set a
    notification function using
    <code class="literal">dbus_g_pending_call_set_notify</code>.
    </p></div><div class="sect2" title="Connecting to object
signals"><div class="titlepage"><div><div><h3 class="title"><a
name="glib-signal-connection"></a>Connecting to object
signals</h3></div></div></div><p>
    You may connect to signals using
    <code class="literal">dbus_g_proxy_add_signal</code> and
    <code class="literal">dbus_g_proxy_connect_signal</code>. You
must
    invoke <code class="literal">dbus_g_proxy_add_signal</code> to
specify
    the signature of your signal handlers; you may then invoke
    <code class="literal">dbus_g_proxy_connect_signal</code> multiple
times.
    </p><p>
    Note that it will often be the case that there is no builtin
marshaller for the type signature of a remote signal. In that
case, you must generate a marshaller yourself by using
<span class="application">glib-genmarshal</span>, and then
register
    it using <code
class="literal">dbus_g_object_register_marshaller</code>.
    </p></div><div class="sect2" title="Error handling and remote
exceptions"><div class="titlepage"><div><div><h3 class="title"><a
name="glib-error-handling"></a>Error handling and remote
exceptions</h3></div></div></div><p>
    All of the GLib binding methods such as
    <code class="literal">dbus_g_proxy_end_call</code> return a
    <code class="literal">GError</code>. This <code
class="literal">GError</code> can
    represent two different things:
    </p><div class="itemizedlist"><ul class="itemizedlist"
type="disc"><li class="listitem"><p>
        An internal D-Bus error, such as an out-of-memory
        condition, an I/O error, or a network timeout. Errors
        generated by the D-Bus library itself have the domain
        <code class="literal">DBUS_GERROR</code>, and a corresponding
code
        such as <code class="literal">DBUS_GERROR_NO_MEMORY</code>.
It will
        not be typical for applications to handle these errors
        specifically.
    </p></li><li class="listitem"><p>
        A remote D-Bus exception, thrown by the peer, bus, or
        service. D-Bus remote exceptions have both a textual
        "name" and a "message". The GLib bindings store this
        information in the <code class="literal">GError</code>, but
some
        special rules apply.

```

</p><p>

The set error will have the domain

<code class="literal">DBUS_GERROR</code> as above, and will

also

have the code

<code class="literal">DBUS_GERROR_REMOTE_EXCEPTION</code>.

In order

to access the remote exception name, you must use a special accessor, such as

<code class="literal">dbus_g_error_has_name</code> or

<code class="literal">dbus_g_error_get_name</code>. The

remote

exception detailed message is accessible via the regular GError <code class="literal">message</code> member.

</p></div><p>

    else
        ...
    g_value_unset (&val);

```

Generated Bindings

Generated Bindings

By using the Introspection XML files, convenient client-side bindings can be automatically created to ease the use of a remote Dbus object.

Here is a sample XML file which describes an object that exposes one method, named `ManyArgs`.

```

<?xml version="1.0" encoding="UTF-8" ?>
<node name="/com/example/MyObject">
  <interface name="com.example.MyObject">
    <method name="ManyArgs">
      <arg type="u" name="x" direction="in" />
      <arg type="s" name="str" direction="in" />
      <arg type="d" name="trouble" direction="in" />
      <arg type="d" name="d_ret" direction="out" />
      <arg type="s" name="str_ret" direction="out" />
    </method>
  </interface>
</node>

```

Run `dbus-binding-tool --mode=glib-client` `FILENAME` `HEADER_NAME` to generate the header

file. For example: `dbus-binding-tool --mode=glib-client my-object.xml > my-object-bindings.h`.

This will generate inline functions with the following prototypes:

```

/* This is a blocking call */

```

```

gboolean
com_example_MyObject_many_args (DBusGProxy *proxy, const guint IN_x,
                                const char * IN_str, const gdouble
IN_trouble,
                                gdouble* OUT_d_ret, char **
OUT_str_ret,
                                GError **error);

```

```

/* This is a non-blocking call */
DBusGProxyCall*
com_example_MyObject_many_args_async (DBusGProxy *proxy, const guint
IN_x,
                                const char * IN_str, const
gdouble IN_trouble,
com_example_MyObject_many_args_reply callback,
                                gpointer userdata);

```

```

/* This is the typedef for the non-blocking callback */
typedef void
(*com_example_MyObject_many_args_reply)
(DBusGProxy *proxy, gdouble OUT_d_ret, char * OUT_str_ret,
 GError *error, gpointer userdata);

```

The first argument in all functions is a `DBusGProxy` class="literal">DBusGProxy, which you should create with the usual `dbus_g_proxy_new_*` class="literal">dbus_g_proxy_new_ functions. Following that are the "in" arguments, and then either the "out" arguments and a `GError *` class="literal">GError * for the synchronous (blocking) function, or callback and user data arguments for the asynchronous (non-blocking) function. The callback in the asynchronous function passes the `DBusGProxy *` class="literal">DBusGProxy *, the returned "out" arguments, an `GError *` class="literal">GError * which is set if there was an error otherwise `NULL` class="literal">NULL, and the user data.

As with the server-side bindings support (see [the section called "GLib API: Implementing Objects"](#glib-server "GLib API: Implementing Objects")), the exact behaviour of the client-side bindings can be manipulated using "annotations". Currently the only annotation used by the client bindings is `org.freedesktop.DBus.GLib.NoReply` class="literal">org.freedesktop.DBus.GLib.NoReply, which sets the

flag indicating that the client isn't expecting a reply to the method call, so a reply shouldn't be sent. This is often used to speed up rapid method calls where there are no "out" arguments, and not knowing if the method succeeded is an acceptable compromise to half the traffic on the bus.

```
</p></div></div><div class="sect1" title="GLib API: Implementing Objects"><div class="titlepage"><div><div><h2 class="title" style="clear: both"><a name="glib-server"></a>GLib API: Implementing Objects</h2></div></div></div><p>
```

At the moment, to expose a GObject via D-Bus, you must write XML by hand which describes the methods exported by the object. In the future, this manual step will be obviated by the upcoming GLib introspection support.

```
</p><p>
```

Here is a sample XML file which describes an object that exposes one method, named `ManyArgs`.

```
</p><pre class="programlisting">
```

```
&lt;?xml version="1.0" encoding="UTF-8" ?&gt;
```

```
&lt;node name="/com/example/MyObject"&gt;
```

```
  &lt;interface name="com.example.MyObject"&gt;
```

```
    &lt;annotation name="org.freedesktop.DBus.GLib.CSymbol" value="my_object"/&gt;
```

```
    &lt;method name="ManyArgs"&gt;
```

```
      &lt;!-- This is optional, and in this case is redundant --&gt;
```

```
      &lt;annotation name="org.freedesktop.DBus.GLib.CSymbol" value="my_object_many_args"/&gt;
```

```
      &lt;arg type="u" name="x" direction="in" /&gt;
```

```
      &lt;arg type="s" name="str" direction="in" /&gt;
```

```
      &lt;arg type="d" name="trouble" direction="in" /&gt;
```

```
      &lt;arg type="d" name="d_ret" direction="out" /&gt;
```

```
      &lt;arg type="s" name="str_ret" direction="out" /&gt;
```

```
    &lt;/method>
```

```
  &lt;/interface>
```

```
&lt;/node>
```

```
</pre><p>
```

```
</p><p>
```

This XML is in the same format as the D-Bus introspection XML format. Except we must include an "annotation" which give the C symbols corresponding to the object implementation prefix (`my_object`). In addition, if

particular

methods symbol names deviate from C convention

(i.e. `ManyArgs` ->

`many_args`), you may specify an

annotation

giving the C symbol.

</p><p>

Once you have written this XML, run `dbus-binding-tool --mode=glib-server <em class="replaceable"><code>FILENAME</code> > <em class="replaceable"><code>HEADER_NAME</code>.</code> to generate a header file. For example: dbus-binding-tool --mode=glib-server my-object.xml > my-object-glue.h.`

</p><p>

Next, include the generated header in your program, and invoke `dbus_g_object_class_install_info` in the class initializer, passing the object class and "object info" included in the

header. For example:

```
dbus_g_object_type_install_info (COM_FOO_TYPE_MY_OBJECT,
&amp;com_foo_my_object_info);
```

This should be done exactly once per object class.

</p><p>

To actually implement the method, just define a C function named e.g.

`my_object_many_args` in the same file as the info

header is included. At the moment, it is required that this function

conform to the following rules:

- <p><div class="itemizedlist"><ul class="itemizedlist" type="disc"><li class="listitem"><p>

The function must return a value of type `gboolean`;

`TRUE` on success, and `FALSE`

otherwise.

- <p><li class="listitem"><p>

The first parameter is a pointer to an instance of the object.

- <p><li class="listitem"><p>

Following the object instance pointer are the method input values.

- <p><li class="listitem"><p>

Following the input values are pointers to return values.

- <p><li class="listitem"><p>

The final parameter must be a `GError**`.

If the function returns `FALSE` for an

error, the error parameter must be initialized with

`g_set_error`.

- <p><p>

</p><p>

Finally, you can export an object using `dbus_g_connection_register_g_object`. For example:

```
dbus_g_connection_register_g_object (connection,
                                     "/com/foo/MyObject",
                                     obj);
```

Server-side Annotations

Server-side Annotations

There are several annotations that are used when generating the

server-side bindings. The most common annotation is `org.freedesktop.DBus.GLib.CSymbol` but there are other annotations which are often useful.

`org.freedesktop.DBus.GLib.CSymbol`

This annotation is used to specify the C symbol names for the various types (interface, method, etc), if it differs from the name DBus generates.

`org.freedesktop.DBus.GLib.Async`

This annotation marks the method implementation as an asynchronous function, which doesn't return a response straight away but will send the response at some later point to complete the call. This is used to implement non-blocking services where method calls can take time.

When a method is asynchronous, the function prototype is different. It is required that the function conform to the following rules:

- The function must return a value of type `gboolean`; `TRUE` on success, and `FALSE` otherwise. TODO: the return value is currently ignored.

The first parameter is a pointer to an instance of the object.

Following the object instance pointer are the method input values.

The final parameter must be a `DBusGMethodInvocation`. This is used when sending the response message back to the client, by

calling `dbus_g_method_return` or `dbus_g_method_return_error`.

This attribute can only be applied to "out"

`&arg` nodes, and specifies that the parameter isn't being copied when returned. For example, this

turns a 's' argument from a `char **` to a `const char **`, and results in the argument not being freed by DBus after the message is sent.

This attribute can only be applied to "out" `&arg` nodes, and alters the expected

function signature. It currently can be set to two values: `""` or `"error"`. The

argument marked with this attribute is not returned via a pointer argument, but by the function's return value.

If the attribute's value is the empty string, the `GError` argument is also omitted so there is no standard way to return an error value. This is very useful for interfacing with existing code, as it is possible to match existing APIs.

If the attribute's value is `"error"`, then the final argument is a `GError *` as usual.

Some examples to demonstrate the usage. This introspection XML:

```
<pre class="programlisting">
<method name="Increment">
  <arg type="u" name="x" />
  <arg type="u" direction="out" />
</method>
```

Expects the following function declaration:

```
gboolean
my_object_increment (MyObject *obj, gint32 x, gint32 *ret, GError
**error);
```

```
</pre>
This introspection XML:
<pre class="programlisting">
<method name="IncrementRetVal">
  <arg type="u" name="x" />
  <arg type="u" direction="out" />
  <annotation name="org.freedesktop.DBus.GLib.ReturnVal"
value="" />
  </arg>
</method>
```

Expects the following function declaration:

```
</pre>
gint32
my_object_increment_retval (MyObject *obj, gint32 x)
```

```
</pre>
This introspection XML:
<pre class="programlisting">
<method name="IncrementRetValError">
  <arg type="u" name="x" />
  <arg type="u" direction="out" />
  <annotation name="org.freedesktop.DBus.GLib.ReturnVal"
value="error" />
  </arg>
</method>
```

Expects the following function declaration:

```
</pre>
gint32
my_object_increment_retval_error (MyObject *obj, gint32 x, GError
**error)
```

```
</pre>
```

```

        </p></dd></dl></div><p>

    <title>Tutorial Work In Progress</title>

    <para>
        This tutorial is not complete; it probably contains some useful
        information, but
        also has plenty of gaps. Right now, you'll also need to refer to
        the D-Bus specification,
        Doxygen reference documentation, and look at some examples of
        how other apps use D-Bus.
    </para>

    <para>
        Enhancing the tutorial is definitely encouraged - send your
        patches or suggestions to the
        mailing list. If you create a D-Bus binding, please add a
        section to the tutorial for your
        binding, if only a short section with a couple of examples.
    </para>

</sect1>

<sect1 id="whatis">
    <title>What is D-Bus?</title>
    <para>
        D-Bus is a system for <firstterm>interprocess
        communication</firstterm>
        (IPC). Architecturally, it has several layers:

        <itemizedlist>
            <listitem>
                <para>

```

A library, `libdbus`, that allows two applications to connect to each other and exchange messages.

A `message bus daemon` executable, built on `libdbus`, that multiple applications can connect to. The daemon can route messages from one application to zero or more other applications.

`Wrapper libraries` or `bindings` based on particular application frameworks. For example, `libdbus-glib` and `libdbus-qt`. There are also bindings to languages such as Python. These wrapper libraries are the API most people should use, as they simplify the details of D-Bus programming. `libdbus` is intended to be a low-level backend for the higher level bindings. Much of the `libdbus` API is only useful for binding implementation.

`libdbus` only supports one-to-one connections, just like a raw network socket. However, rather than sending byte streams over the connection, you send `messages`. Messages have a header identifying the kind of message, and a body containing a data payload. `libdbus` also abstracts the exact transport used (sockets vs. whatever else), and handles details such as authentication.

The message bus daemon forms the hub of a wheel. Each spoke of the wheel

is a one-to-one connection to an application using libdbus. An application sends a message to the bus daemon over its spoke, and the bus daemon forwards the message to other connected applications as appropriate. Think of the daemon as a router.

The first instance is a machine-global singleton, that is, a system daemon similar to sendmail or Apache. This instance has heavy security restrictions on what messages it will accept, and is used for systemwide communication. The other instances are created one per user login session. These instances allow applications in the user's session to communicate with one another.

The systemwide and per-user daemons are separate. Normal within-session IPC does not involve the systemwide message bus process and vice versa.

D-Bus applications

There are many, many technologies in the world that have "Inter-process communication" or "networking" in their stated purpose: [CORBA](http://www.omg.org), [DCE](http://www.opengroup.org/dce/), [DCOM](http://www.microsoft.com/com/), [DCOP](http://developer.kde.org/documentation/library/kdeqt/dcop.html), [XML-RPC](http://www.xmlrpc.com), [SOAP](http://www.w3.org/TR/SOAP/), [MBUS](http://www.mbus.org), [Internet Communications Engine \(ICE\)](http://www.zeroc.com/ice.html), and probably hundreds more. Each of these is tailored for particular kinds of application. D-Bus is designed for two specific cases:

-
-

desktop
a whole,
components

Communication between desktop applications in the same session; to allow integration of the desktop session as a whole, and address issues of process lifecycle (when do desktop components start and stop running).

</para>
</listitem>
<listitem>
<para>
operating system,
kernel

Communication between the desktop session and the where the operating system would typically include the and any system daemons or processes.

</para>
</listitem>
</itemizedlist>
</para>
<para>
desktops
solutions

For the within-desktop-session use case, the GNOME and KDE have significant previous experience with different IPC solutions such as CORBA and DCOP. D-Bus is built on that experience and carefully tailored to meet the needs of these desktop projects in particular. D-Bus may or may not be appropriate for other applications; the FAQ has some comparisons to other IPC systems.

</para>
<para>
the-OS case
project:

The problem solved by the systemwide or communication-with-the-OS case is explained well by the following text from the Linux Hotplug project:

<blockquote>
<para>
sort of
a network
appropriate places
be
identified:

A gap in current Linux support is that policies with any dynamic "interact with user" component aren't currently supported. For example, that's often needed the first time adapter or printer is connected, and to determine appropriate places to mount disk drives. It would seem that such actions could be supported for any case where a responsible human can be identified: single user workstations, or any system which is remotely administered.

</para>

<para>
This is a classic "remote sysadmin" problem, where in this
case hotplugging needs to deliver an event from one security
domain (operating system kernel, in this case) to another
(desktop for logged-in user, or remote sysadmin). Any effective
response must go the other way: the remote domain taking some action that
lets the kernel expose the desired device capabilities. (The action
can often be taken asynchronously, for example letting new hardware
be idle until a meeting finishes.) At this writing, Linux doesn't
have widely adopted solutions to such problems. However, the
new D-Bus work may begin to solve that problem.

</para>
</blockquote>
</para>
<para>

D-Bus may happen to be useful for purposes other than the one
it was designed for. Its general properties that distinguish it from
other forms of IPC are:

- <itemizedlist>
 - <listitem>
 - <para>
Binary protocol designed to be used asynchronously
(similar in spirit to the X Window System protocol).
 - </para>
 - </listitem>
 - <listitem>
 - <para>
Stateful, reliable connections held open over time.
 - </para>
 - </listitem>
 - <listitem>
 - <para>
The message bus is a daemon, not a "swarm" or
distributed architecture.
 - </para>
 - </listitem>
 - <listitem>
 - <para>
Many implementation and deployment issues are specified
 - </listitem>

rather than left ambiguous/configurable/pluggable.

```

        </para>
    </listitem>
    <listitem>
        <para>
            Semantics are similar to the existing DCOP system,
allowing
            KDE to adopt it more easily.
        </para>
    </listitem>
    <listitem>
        <para>
            Security features to support the systemwide mode of the
            message bus.
        </para>
    </listitem>
</itemizedlist>
</para>
</sect2>
</sect1>
<sect1 id="concepts">
    <title>Concepts</title>
    <para>
        Some basic concepts apply no matter what application framework
you're
        using to write a D-Bus application. The exact code you write
will be
        different for GLib vs. Qt vs. Python applications, however.
    </para>

    <para>
        Here is a diagram (<ulink url="diagram.png">png</ulink> <ulink
        url="diagram.svg">svg</ulink>) that may help you visualize the
concepts
        that follow.
    </para>

    <sect2 id="objects">
        <title>Native Objects and Object Paths</title>
        <para>
            Your programming framework probably defines what an "object"
is like;
            usually with a base class. For example: java.lang.Object,
GObject, QObject,
            python's base Object, or whatever. Let's call this a
<firstterm>native object</firstterm>.
        </para>
        <para>
            The low-level D-Bus protocol, and corresponding libdbus API,
does not care about native objects.
            However, it provides a concept called an
            <firstterm>object path</firstterm>. The idea of an object path
is that

```

higher-level bindings can name native object instances, and allow remote applications to refer to them.

</para>

<para>

The object path looks like a filesystem path, for example an object could be named <literal>/org/kde/kspread/sheets/3/cells/4/5</literal>. Human-readable paths are nice, but you are free to create an object named

<literal>/com/mycompany/c5yo817y0c1y1c5b</literal>

if it makes sense for your application.

</para>

<para>

Namespacing object paths is smart, by starting them with the components

of a domain name you own (e.g. <literal>/org/kde</literal>).

This

keeps different code modules in the same process from stepping on one another's toes.

</para>

</sect2>

<sect2 id="members">

<title>Methods and Signals</title>

<para>

Each object has <firstterm>members</firstterm>; the two kinds of member

are <firstterm>methods</firstterm> and

<firstterm>signals</firstterm>. Methods are operations that can be

invoked on an object, with optional input (aka arguments or "in

parameters") and output (aka return values or "out parameters").

Signals are broadcasts from the object to any interested observers

of the object; signals may contain a data payload.

</para>

<para>

Both methods and signals are referred to by name, such as "Frobate" or "OnClicked".

</para>

</sect2>

<sect2 id="interfaces">

<title>Interfaces</title>

<para>

Each object supports one or more
<firstterm>interfaces</firstterm>.

Think of an interface as a named group of methods and signals, just as it is in GLib or Qt or Java. Interfaces define the <emphasis>type</emphasis> of an object instance.

</para>

<para>

DBus identifies interfaces with a simple namespaced string, something like

<literal>org.freedesktop.Introspectable</literal>.

Most bindings will map these interface names directly to the appropriate programming language construct, for example to Java interfaces or C++ pure virtual classes.

</para>

</sect2>

<sect2 id="proxies">

<title>Proxies</title>

<para>

A <firstterm>proxy object</firstterm> is a convenient native object created to

represent a remote object in another process. The low-level DBus API involves manually creating

a method call message, sending it, then manually receiving and processing

the method reply message. Higher-level bindings provide proxies as an alternative.

Proxies look like a normal native object; but when you invoke a method on the proxy

object, the binding converts it into a DBus method call message, waits for the reply

message, unpacks the return value, and returns it from the native method..

</para>

<para>

In pseudocode, programming without proxies might look like this:

<programlisting>

```
Message message = new Message("/remote/object/path",  
"MethodName", arg1, arg2);
```

```
Connection connection = getBusConnection();
```

```
connection.send(message);
```

```
Message reply = connection.waitForReply(message);
```

```
if (reply.isError()) {
```

```
    } else {
```

```
        Object returnValue = reply.getReturnValue();
```

```
    }
```

</programlisting>

</para>

<para>

Programming with proxies might look like this:

```
    <programlisting>
        Proxy proxy = new Proxy(getBusConnection(),
"/remote/object/path");
        Object returnValue = proxy.MethodName(arg1, arg2);
    </programlisting>
</para>
</sect2>
```

```
<sect2 id="bus-names">
  <title>Bus Names</title>
```

```
  <para>
    When each application connects to the bus daemon, the daemon
immediately
    assigns it a name, called the <firstterm>unique connection
name</firstterm>.
    A unique name begins with a ':' (colon) character. These names
are never
    reused during the lifetime of the bus daemon - that is, you
know
    a given name will always refer to the same application.
    An example of a unique name might be
    <literal>:34-907</literal>. The numbers after the colon have
no meaning other than their uniqueness.
  </para>
```

```
  <para>
    When a name is mapped
    to a particular application's connection, that application is
said to
    <firstterm>own</firstterm> that name.
  </para>
```

```
  <para>
    Applications may ask to own additional <firstterm>well-known
names</firstterm>. For example, you could write a
specification to
    define a name called
<literal>com.mycompany.TextEditor</literal>.
    Your definition could specify that to own this name, an
application
    should have an object at the path
    <literal>/com/mycompany/TextFileManager</literal> supporting
the
    interface <literal>org.freedesktop.FileHandler</literal>.
  </para>
```

```
  <para>
    Applications could then send messages to this bus name,
object, and interface to execute method calls.
  </para>
```

```
<para>
  You could think of the unique names as IP addresses, and the
  well-known names as domain names. So
  <literal>com.mycompany.TextEditor</literal> might map to
something like
  <literal>:34-907</literal> just as
<literal>mycompany.com</literal> maps
  to something like <literal>192.168.0.5</literal>.
</para>
```

```
<para>
  Names have a second important use, other than routing
messages. They
  are used to track lifecycle. When an application exits (or
crashes), its
  connection to the message bus will be closed by the operating
system
  kernel. The message bus then sends out notification messages
telling
  remaining applications that the application's names have lost
their
  owner. By tracking these notifications, your application can
reliably
  monitor the lifetime of other applications.
</para>
```

```
<para>
  Bus names can also be used to coordinate single-instance
applications.
  If you want to be sure only one
  <literal>com.mycompany.TextEditor</literal> application is
running for
  example, have the text editor application exit if the bus name
already
  has an owner.
</para>
```

```
</sect2>
```

```
<sect2 id="addresses">
  <title>Addresses</title>
```

```
<para>
  Applications using D-Bus are either servers or clients. A
server
  listens for incoming connections; a client connects to a
server. Once
  the connection is established, it is a symmetric flow of
messages; the
  client-server distinction only matters when setting up the
connection.
</para>
```

`<para>`
If you're using the bus daemon, as you probably are, your application will be a client of the bus daemon. That is, the bus daemon listens for connections and your application initiates a connection to the bus daemon.
`</para>`

`<para>`
A D-Bus `<firstterm>address</firstterm>` specifies where a server will listen, and where a client will connect. For example, the address `<literal>unix:path=/tmp/abcdef</literal>` specifies that the server will listen on a UNIX domain socket at the path `<literal>/tmp/abcdef</literal>` and the client will connect to that socket. An address can also specify TCP/IP sockets, or any other transport defined in future iterations of the D-Bus specification.
`</para>`

`<para>`
When using D-Bus with a message bus daemon, `libdbus` automatically discovers the address of the per-session bus daemon by reading an environment variable. It discovers the systemwide bus daemon by checking a well-known UNIX domain socket path (though you can override this address with an environment variable).
`</para>`

`<para>`
If you're using D-Bus without a bus daemon, it's up to you to define which application will be the server and which will be the client, and specify a mechanism for them to agree on the server's address. This is an unusual case.
`</para>`

`</sect2>`

`<sect2 id="bigpicture">`
`<title>Big Conceptual Picture</title>`

`<para>`
Pulling all these concepts together, to specify a particular

method call on a particular object instance, a number of nested components have to be named:

```
<programlisting>
```

```
    Address -&gt; [Bus Name] -&gt; Path -&gt; Interface -&gt;
```

Method

```
</programlisting>
```

The bus name is in brackets to indicate that it's optional -- you only

provide a name to route the method call to the right application

when using the bus daemon. If you have a direct connection to another

application, bus names aren't used; there's no bus daemon.

```
</para>
```

```
<para>
```

The interface is also optional, primarily for historical reasons; DCOP does not require specifying the interface, instead simply forbidding duplicate method names on the same object instance. D-Bus will thus let you omit the interface, but if your method name is ambiguous it is undefined which method will be invoked.

```
</para>
```

```
</sect2>
```

```
<sect2 id="messages">
```

```
<title>Messages - Behind the Scenes</title>
```

```
<para>
```

D-Bus works by sending messages between processes. If you're using

a sufficiently high-level binding, you may never work with messages directly.

```
</para>
```

```
<para>
```

There are 4 message types:

```
<itemizedlist>
```

```
<listitem>
```

```
<para>
```

Method call messages ask to invoke a method on an object.

```
</para>
```

```
</listitem>
```

```
<listitem>
```

```
<para>
```

Method return messages return the results of invoking a method.

```
</para>
```

```
</listitem>
```

```
<listitem>
```

```
<para>
```

Error messages return an exception caused by

```

        invoking a method.
    </para>
</listitem>
<listitem>
    <para>
        Signal messages are notifications that a given signal
        has been emitted (that an event has occurred).
        You could also think of these as "event" messages.
    </para>
</listitem>
</itemizedlist>
</para>
<para>
    A method call maps very simply to messages: you send a method
call
    message, and receive either a method return message or an
error message
    in reply.
</para>
<para>
    Each message has a <firstterm>header</firstterm>, including
<firstterm>fields</firstterm>,
    and a <firstterm>body</firstterm>, including
<firstterm>arguments</firstterm>. You can think
    of the header as the routing information for the message, and
the body as the payload.
    Header fields might include the sender bus name, destination
bus name, method or signal name,
    and so forth. One of the header fields is a <firstterm>type
signature</firstterm> describing the
    values found in the body. For example, the letter "i" means
"32-bit integer" so the signature
    "ii" means the payload has two 32-bit integers.
</para>
</sect2>

<sect2 id="callprocedure">
    <title>Calling a Method - Behind the Scenes</title>

    <para>
        A method call in Dbus consists of two messages; a method call
message sent from process A to process B,
        and a matching method reply message sent from process B to
process A. Both the call and the reply messages
        are routed through the bus daemon. The caller includes a
different serial number in each call message, and the
        reply message includes this number to allow the caller to
match replies to calls.
    </para>

    <para>
        The call message will contain any arguments to the method.

```

The reply message may indicate an error, or may contain data returned by the method.

</para>

<para>

A method invocation in DBus happens as follows:

<itemizedlist>

<listitem>

<para>

The language binding may provide a proxy, such that invoking a method on an in-process object invokes a method on a remote object in another process. If so, the application calls a method on the proxy, and the proxy constructs a method call message to send to the remote process.

</para>

</listitem>

<listitem>

<para>

For more low-level APIs, the application may construct a method call message itself, without using a proxy.

</para>

</listitem>

<listitem>

<para>

In either case, the method call message contains: a bus name belonging to the remote process; the name of the method; the arguments to the method; an object path inside the remote process; and optionally the name of the interface that specifies the method.

</para>

</listitem>

<listitem>

<para>

The method call message is sent to the bus daemon.

</para>

</listitem>

<listitem>

<para>

The bus daemon looks at the destination bus name. If a process owns that name, the bus daemon forwards the method call to that process. Otherwise, the bus daemon creates an error message and sends it back as the reply to the method call message.

</para>

</listitem>

<listitem>

<para>

The receiving process unpacks the method call message. In a simple low-level API situation, it may immediately run the method and send a method reply message to the bus daemon.

When using a high-level binding API, the binding might examine the object path, interface, and method name, and convert the method call message into an invocation of a method on a native object (GObject, java.lang.Object, QObject, etc.), then convert the return value from the native method into a method reply message.

```
</para>
</listitem>
<listitem>
```

The bus daemon receives the method reply message and sends it to the process that made the method call.

```
</para>
</listitem>
<listitem>
```

The process that made the method call looks at the method reply and makes use of any return values included in the reply. The reply may also indicate that an error occurred.

When using a binding, the method reply message may be converted into the return value of a proxy method, or into an exception.

```
</para>
</listitem>
</itemizedlist>
</para>
```

The bus daemon never reorders messages. That is, if you send two method call messages to the same recipient, they will be received in the order they were sent. The recipient is not required to reply to the calls in order, however; for example, it may process each method call in a separate thread, and return reply messages in an undefined order depending on when the threads complete. Method calls have a unique serial number used by the method caller to match reply messages to call messages.

```
</para>
```

```
</sect2>
```

```
<sect2 id="signalprocedure">
```

```
<title>Emitting a Signal - Behind the Scenes</title>
```

<para>

A signal in Dbus consists of a single message, sent by one process to any number of other processes.

That is, a signal is a unidirectional broadcast. The signal may contain arguments (a data payload), but

because it is a broadcast, it never has a "return value."

Contrast this with a method call

(see <xref linkend="callprocedure"/>) where the method call message has a matching method reply message.

</para>

<para>

The emitter (aka sender) of a signal has no knowledge of the signal recipients. Recipients register

with the bus daemon to receive signals based on "match rules"

- these rules would typically include the sender and

the signal name. The bus daemon sends each signal only to recipients who have expressed interest in that signal.

</para>

<para>

A signal in Dbus happens as follows:

<itemizedlist>

<listitem>

<para>

A signal message is created and sent to the bus daemon. When using the low-level API this may be

done manually, with certain bindings it may be done for you by the binding when a native object

emits a native signal or event.

</para>

</listitem>

<listitem>

<para>

The signal message contains the name of the interface that specifies the signal;

the name of the signal; the bus name of the process sending the signal; and

any arguments

</para>

</listitem>

<listitem>

<para>

Any process on the message bus can register "match rules" indicating which signals it

is interested in. The bus has a list of registered match rules.

</para>

</listitem>

</listitem>

```

    <para>
        The bus daemon examines the signal and determines which
processes are interested in it.
        It sends the signal message to these processes.
    </para>
</listitem>
<listitem>
    <para>
        Each process receiving the signal decides what to do
with it; if using a binding,
        the binding may choose to emit a native signal on a
proxy object. If using the
        low-level API, the process may just look at the signal
sender and name and decide
        what to do based on that.
    </para>
</listitem>
</itemizedlist>
</para>

```

```

</informaltable>

As you can see, the basic mapping is fairly straightforward.

</para>

</sect3>

<sect3 id="glib-container-typemappings">

<title>Container type mappings</title>

<para>

The D-Bus type system also has a number of "container" types, such as <literal>DBUS_TYPE_ARRAY</literal> and <literal>DBUS_TYPE_STRUCT</literal>. The D-Bus type system is fully recursive, so one can for example have an array of array of strings (i.e. type signature <literal>aas</literal>).

</para>

<para>

However, not all of these types are in common use; for example, at the time of this writing the author knows of no one using <literal>DBUS_TYPE_STRUCT</literal>, or a <literal>DBUS_TYPE_ARRAY</literal> containing any non-basic type. The approach the GLib bindings take is pragmatic; try

to map the most common types in the most obvious way, and let using less common and more complex types be less "natural".

</para>

<para>

First, D-Bus type signatures which have an "obvious" corresponding built-in GLib type are mapped using that type:

<informaltable>

<entry>The calling conventions for values expect that

method callers have allocated return values; see below.</entry>

</row>

</tbody>

</tgroup>

</informaltable>

</para>

<para>

The next most common recursive type signatures are arrays of basic values. The most obvious mapping for arrays of basic types is a <literal>GArray</literal>. Now, GLib does not provide a builtin <literal>GType</literal> for <literal>GArray</literal>. However, we actually need more than that - we need a "parameterized" type which includes the contained type. Why we need this we will see below.

</para>

<para>

The approach taken is to create these types in the D-Bus GLib bindings; however, there is nothing D-Bus specific about them.

GLib

In the future, we hope to include such "fundamental" types in itself.

</tbody>
</tgroup>
</informaltable>

```

</para>

<para>

D-Bus also includes a special type `DBUS_TYPE_DICT_ENTRY` which is only valid in arrays. It's intended to be mapped to a "dictionary" type by bindings. The obvious GLib mapping here is `GHashTable`.

Again,

however, there is no builtin `GType` for a `GHashTable`.

Moreover, just like for arrays, we need a parameterized type so that

the bindings can communicate which types are contained in the hash table.

</para>

<para>

At present, only strings are supported. Work is in progress to include more types.

  <title>Program initialization</title>
  <para>
    A connection to the bus is acquired using
    <literal>dbus_g_bus_get</literal>. Next, a proxy
    is created for the object "/org/freedesktop/DBus" with
    interface <literal>org.freedesktop.DBus</literal>
    on the service <literal>org.freedesktop.DBus</literal>.
    This is a proxy for the message bus itself.
  </para>
</sect2>
<sect2 id="glib-method-invocation">
  <title>Understanding method invocation</title>
  <para>
    You have a number of choices for method invocation. First, as
    used above, <literal>dbus_g_proxy_call</literal> sends a
    method call to the remote object, and blocks until a reply is
    recieved. The outgoing arguments are specified in the varargs
    array, terminated with <literal>G_TYPE_INVALID</literal>.
    Next, pointers to return values are specified, followed again
    by <literal>G_TYPE_INVALID</literal>.
  </para>
  <para>
    To invoke a method asynchronously, use
    <literal>dbus_g_proxy_begin_call</literal>. This returns a
    <literal>DBusGPendingCall</literal> object; you may then set a
    notification function using
    <literal>dbus_g_pending_call_set_notify</literal>.
  </para>
</sect2>
<sect2 id="glib-signal-connection">
  <title>Connecting to object signals</title>
  <para>
    You may connect to signals using
    <literal>dbus_g_proxy_add_signal</literal> and
    <literal>dbus_g_proxy_connect_signal</literal>. You must
    invoke <literal>dbus_g_proxy_add_signal</literal> to specify
    the signature of your signal handlers; you may then invoke
    <literal>dbus_g_proxy_connect_signal</literal> multiple times.
  </para>
  <para>
    Note that it will often be the case that there is no builtin
    marshaller for the type signature of a remote signal. In that
    case, you must generate a marshaller yourself by using
    <application>glib-genmarshal</application>, and then register
    it using <literal>dbus_g_object_register_marshaller</literal>.
  </para>

```

```

<title>Error handling and remote exceptions</title>
<para>
All of the GLib binding methods such as
<literal>dbus_g_proxy_end_call</literal> return a
<literal>GError</literal>. This <literal>GError</literal> can
represent two different things:
<itemizedlist>
<listitem>
<para>
An internal D-Bus error, such as an out-of-memory
condition, an I/O error, or a network timeout. Errors
generated by the D-Bus library itself have the domain
<literal>DBUS_GERROR</literal>, and a corresponding code
such as <literal>DBUS_GERROR_NO_MEMORY</literal>. It will
not be typical for applications to handle these errors
specifically.
</para>
</listitem>
<listitem>
<para>
A remote D-Bus exception, thrown by the peer, bus, or
service. D-Bus remote exceptions have both a textual
"name" and a "message". The GLib bindings store this
information in the <literal>GError</literal>, but some
special rules apply.
</para>
<para>
The set error will have the domain
<literal>DBUS_GERROR</literal> as above, and will also
have the code
<literal>DBUS_GERROR_REMOTE_EXCEPTION</literal>. In order
to access the remote exception name, you must use a
special accessor, such as
<literal>dbus_g_error_has_name</literal> or
<literal>dbus_g_error_get_name</literal>. The remote
exception detailed message is accessible via the regular
GError <literal>message</literal> member.
</para>
</listitem>

(*com_example_MyObject_many_args_reply)
(DBusGProxy *proxy, gdouble OUT_d_ret, char * OUT_str_ret,
 GError *error, gpointer userdata);
</programlisting>
    The first argument in all functions is a <literal>DBusGProxy
    *</literal>, which you should create with the usual
    <literal>dbus_g_proxy_new_*</literal> functions. Following
that are the
    "in" arguments, and then either the "out" arguments and a
    <literal>GError *</literal> for the synchronous (blocking)
function, or
    callback and user data arguments for the asynchronous (non-
blocking)
    function. The callback in the asynchronous function passes
the
    <literal>DBusGProxy *</literal>, the returned "out" arguments,
an
    <literal>GError *</literal> which is set if there was an error
otherwise
    <literal>NULL</literal>, and the user data.
</para>
<para>
    As with the server-side bindings support (see <xref
    linkend="glib-server"/>), the exact behaviour of the client-
side
    bindings can be manipulated using "annotations". Currently
the only
    annotation used by the client bindings is
    <literal>org.freedesktop.DBus.GLib.NoReply</literal>, which
sets the
    flag indicating that the client isn't expecting a reply to the
method
    call, so a reply shouldn't be sent. This is often used to
speed up
    rapid method calls where there are no "out" arguments, and not
knowing
    if the method succeeded is an acceptable compromise to half
the traffic
    on the bus.
    </para>

```

<title>GLib API: Implementing Objects</title>

<para>

At the moment, to expose a GObject via D-Bus, you must write XML by hand which describes the methods exported by the object. In the future, this manual step will be obviated by the upcoming GLib introspection support.

</para>

<para>

Here is a sample XML file which describes an object that exposes one method, named <code>ManyArgs</code>.

<programlisting>

```
<?xml version="1.0" encoding="UTF-8" ?>

<node name="/com/example/MyObject">

  <interface name="com.example.MyObject">
    <annotation name="org.freedesktop.DBus.GLib.CSymbol"
value="my_object"/>
    <method name="ManyArgs">
      <!-- This is optional, and in this case is redundant -->
      <annotation name="org.freedesktop.DBus.GLib.CSymbol"
value="my_object_many_args"/>
      <arg type="u" name="x" direction="in" />
      <arg type="s" name="str" direction="in" />
      <arg type="d" name="trouble" direction="in" />
      <arg type="d" name="d_ret" direction="out" />
      <arg type="s" name="str_ret" direction="out" />
    </method>
  </interface>
</node>
</programlisting>
```

</para>

<para>

This XML is in the same format as the D-Bus introspection XML format. Except we must include an "annotation" which give the C symbols corresponding to the object implementation prefix (<code>my_object</code>). In addition, if particular methods symbol names deviate from C convention (i.e. <code>ManyArgs</code> -> <code>many_args</code>), you may specify an annotation giving the C symbol.

</para>

<para>

Once you have written this XML, run <code>dbus-binding-tool -mode=glib-server <replaceable>FILENAME</replaceable> <replaceable>HEADER_NAME</replaceable></code> to generate a header file. For example: <code>dbus-binding-tool --mode=glib-server my-object.xml <replaceable>my-object-glue.h</replaceable></code>.

</para>

<para>

Next, include the generated header in your program, and invoke <code>dbus_g_object_class_install_info</code> in the class

initializer, passing the object class and "object info" included in the

header. For example:

```
<programlisting>
dbus_g_object_type_install_info (COM_FOO_TYPE_MY_OBJECT,
&amp;com_foo_my_object_info);
</programlisting>
```

This should be done exactly once per object class.

</para>

<para>

To actually implement the method, just define a C function named e.g.

<literal>my_object_many_args</literal> in the same file as the info

header is included. At the moment, it is required that this function

conform to the following rules:

<itemizedlist>

<listitem>

<para>

The function must return a value of type <literal>gboolean</literal>;

<literal>TRUE</literal> on success, and <literal>FALSE</literal>

otherwise.

</para>

</listitem>

<listitem>

<para>

The first parameter is a pointer to an instance of the object.

</para>

</listitem>

<listitem>

<para>

Following the object instance pointer are the method input values.

</para>

</listitem>

<listitem>

<para>

Following the input values are pointers to return values.

</para>

</listitem>

<listitem>

<para>

The final parameter must be a <literal>GError **</literal>.

If the function returns <literal>FALSE</literal> for an

error, the error parameter must be initialized with

<literal>g_set_error</literal>.

</para>

</listitem>

```

    </itemizedlist>
</para>
<para>
    Finally, you can export an object using
<literal>dbus_g_connection_register_g_object</literal>. For example:
    <programlisting>
        dbus_g_connection_register_g_object (connection,
                                           "/com/foo/MyObject",
                                           obj);
    </programlisting>
</para>

<sect2 id="glib-annotations">
    <title>Server-side Annotations</title>
    <para>
        There are several annotations that are used when generating
the
        server-side bindings. The most common annotation is
        <literal>org.freedesktop.DBus.GLib.CSymbol</literal> but there
are other
        annotations which are often useful.
    <variablelist>
        <varlistentry>

<term><literal>org.freedesktop.DBus.GLib.CSymbol</literal></term>
        <listitem>
            <para>
                This annotation is used to specify the C symbol names
for
                the various types (interface, method, etc), if it
differs from the
                name DBus generates.
            </para>
        </listitem>
    </varlistentry>
    <varlistentry>

<term><literal>org.freedesktop.DBus.GLib.Async</literal></term>
        <listitem>
            <para>
                This annotation marks the method implementation as an
straight
                asynchronous function, which doesn't return a response
complete
                away but will send the response at some later point to
services where
                the call. This is used to implement non-blocking
                method calls can take time.
            </para>
            <para>
                When a method is asynchronous, the function prototype
is

```

different. It is required that the function conform to the

following rules:

<itemizedlist>

<listitem>

<para>

The function must return a value of type <literal>gboolean</literal>;

<literal>TRUE</literal> on success, and <literal>FALSE</literal>

otherwise. TODO: the return value is currently ignored.

</para>

</listitem>

<listitem>

<para>

The first parameter is a pointer to an instance of the object.

</para>

</listitem>

<listitem>

<para>

Following the object instance pointer are the method

input values.

</para>

</listitem>

<listitem>

<para>

The final parameter must be a <literal>DBusGMethodInvocation *</literal>.

This is used

when sending the response message back to the client, by

calling <literal>dbus_g_method_return</literal>

or <literal>dbus_g_method_return_error</literal>.

</para>

</listitem>

</itemizedlist>

</para>

</listitem>

</varlistentry>

<varlistentry>

<term><literal>org.freedesktop.DBus.GLib.Const</literal></term>

<listitem>

<para>This attribute can only be applied to "out" <literal><arg></literal> nodes, and specifies that the

parameter isn't being copied when returned. For example, this

turns a 's' argument from a `char **` to a `const char **`, and results in the argument not being freed by DBus after the message is sent.

This attribute can only be applied to "out" `<arg>` nodes, and alters the expected function signature. It currently can be set to two values: `""` or `"error"`. The argument marked with this attribute is not returned via a pointer argument, but by the function's return value. If the attribute's value is the empty string, the `GError` * argument is also omitted so there is no standard way to return an error value. This is very useful for interfacing with existing code, as it is possible to match existing APIs.

If the attribute's value is `"error"`, then the final argument is a `GError *` as usual.

Some examples to demonstrate the usage. This introspection XML:

```

<programlisting>
<method name="Increment">
  <arg type="u" name="x" />
  <arg type="u" direction="out" />
</method>
</programlisting>

```

Expects the following function declaration:

```

<programlisting>
gboolean
my_object_increment (MyObject *obj, gint32 x, gint32 *ret, GError
**error);
</programlisting>

```

```

        </para>
        <para>
            This introspection XML:
            <programlisting>
<method name="IncrementRetVal">
    <arg type="u" name="x" />
    <arg type="u" direction="out" >
        <annotation name="org.freedesktop.DBus.GLib.ReturnVal"
value=""/>
        </arg>
    </method>
    </programlisting>
            Expects the following function declaration:
            <programlisting>
gint32
my_object_increment_retval (MyObject *obj, gint32 x)
    </programlisting>
        </para>
        <para>
            This introspection XML:
            <programlisting>
<method name="IncrementRetValError">
    <arg type="u" name="x" />
    <arg type="u" direction="out" >
        <annotation name="org.freedesktop.DBus.GLib.ReturnVal"
value="error"/>
        </arg>
    </method>
    </programlisting>
            Expects the following function declaration:
            <programlisting>
gint32
my_object_increment_retval_error (MyObject *obj, gint32 x, GError
**error)
    </programlisting>
        </para>
    </listitem>

.\" Copyright (C) 2006 Red Hat, Inc.
.\"
.TH dbus\--uuidgen 1
.SH NAME
dbus\--uuidgen \- Utility to generate UUIDs
.SH SYNOPSIS
.PP
.B dbus\--uuidgen [\--version] [\--ensure[=FILENAME]] [\--get[=FILENAME]]
.SH DESCRIPTION

The \fIdbus\--uuidgen\fP command generates or reads a universally
unique ID.

.PP
Note that the D\--Bus UUID has no relationship to RFC 4122 and does not
generate
UUIDs compatible with that spec. Many systems have a separate command
for that (often called "uuidgen").

.PP
See http://www.freedesktop.org/software/dbus/ for more information
about D\--Bus.

.PP

```

The primary usage of `\fIdbus\--uuidgen\fi` is to run in the post-install

script of a D-Bus package like this:

```
.nf
```

```
dbus\--uuidgen \--ensure
```

```
.fi
```

```
.PP
```

This will ensure that `/var/lib/dbus/machine-id` exists and has the `uuid` in it.

It won't overwrite an existing `uuid`, since this id should remain fixed for a single machine until the next reboot at least.

```
.PP
```

The important properties of the machine UUID are that 1) it remains unchanged until the next reboot and 2) it is different for any two running instances of the OS kernel. That is, if two processes see the same UUID, they should also see the same shared memory, UNIX domain sockets, local X displays, `localhost.localdomain` resolution, process IDs, and so forth.

```
.PP
```

If you run `\fIdbus\--uuidgen\fi` with no options it just prints a new `uuid` made up out of thin air.

```
.PP
```

If you run it with `\--get`, it prints the machine UUID by default, or the UUID in the specified file if you specify a file.

```
.PP
```

If you try to change an existing `machine-id` on a running system, it will probably result in bad things happening. Don't try to change this file. Also, don't make it the same on two different systems; it needs to be different anytime there are two different kernels running.

```
.PP
```

The UUID should be different on two different virtual machines, because there are two different kernels.

```
.SH OPTIONS
```

The following options are supported:

```
.TP
```

```
.I "\--get[=FILENAME]"
```

If a filename is not given, defaults to

`localstatedir/lib/dbus/machine-id`

(`localstatedir` is usually `/var`). If this file exists and is valid, the `uuid` in the file is printed on `stdout`. Otherwise, the command exits with a nonzero status.

```
.TP
.I "\-\-ensure[=FILENAME]"
If a filename is not given, defaults to
localstatedir/lib/dbus/machine\-id
(localstatedir is usually /var). If this file exists then it will be
validated, and a failure code returned if it contains the wrong thing.
If the file does not exist, it will be created with a new uuid in it.
On success, prints no output.
```

```
.TP
.I "\-\-version"
Print the version of dbus\-\-uuidgen
```

```
.SH AUTHOR
See http://www.freedesktop.org/software/dbus/doc/AUTHORS
```

```
.SH BUGS
Please send bug reports to the D\-\-Bus mailing list or bug tracker,
see http://www.freedesktop.org/software/dbus/
```

 * @brief The low-level public API of the D-Bus library
 *
 * libdbus provides a low-level C API intended primarily for use by
 * bindings to specific object systems and languages. D-Bus is most
 * convenient when used with the GLib bindings, Python bindings, Qt
 * bindings, Mono bindings, and so forth. This low-level API has a
 * lot of complexity useful only for bindings.
 *
 * @{
 */

/** @} */

/**
 * @mainpage
 *
 * This manual documents the low-level D-Bus C API. If you
 use
 * this low-level API directly, you're signing up for some pain.
 *
 * Caveats aside, you might get started learning the low-level API by
 reading
 * about @ref DBusConnection and @ref DBusMessage.
 *
 * There are several other places to look for D-Bus information, such
 * as the tutorial and the specification; those can be found at the D-Bus
 \* website. If you're interested in a sysadmin or package
 * maintainer's perspective on the dbus-daemon itself and its
 * configuration, be sure to check out the man pages as well.
 *
 * The low-level API documented in this manual deliberately lacks
 * most convenience functions - those are left up to higher-level
 libraries
 * based on frameworks such as GLib, Qt, Python, Mono, Java,
 * etc. These higher-level libraries (often called "D-Bus bindings")
 * have features such as object systems and main loops that allow a

```

```

* <em>much</em> more convenient API.
*
* The low-level API also contains plenty of clutter to support
* integration with arbitrary object systems, languages, main loops,
* and so forth. These features add a lot of noise to the API that you
* probably don't care about unless you're coding a binding.
*
* This manual also contains docs for @ref DBusInternals "D-Bus
internals",
* so you can use it to get oriented to the D-Bus source code if
you're
* interested in patching the code. You should also read the
* file HACKING which comes with the source code if you plan to
contribute to
* D-Bus.
*
* As you read the code, you can identify internal D-Bus functions
* because they start with an underscore ('_') character. Also, any
* identifier or macro that lacks a DBus, dbus_, or DBUS_ namespace
* prefix is internal, with a couple of exceptions such as #NULL,
* #TRUE, and #FALSE.

DCOP: Desktop COmmunications Protocol

Preston Brown <pbrown@kde.org>
October 14, 1999

Revised and extended by Matthias Ettrich <ettrich@kde.org>
Mar 29, 2000

Extended with DCOP Signals by Waldo Bastian <bastian@kde.org>
Feb 19, 2001

Motivation and Background:

The motivation behind building a protocol like DCOP is simple. For the past year, we have been attempting to enable interprocess communication between KDE applications. KDE already has an extremely simple IPC mechanism called KWMcom, which is (was!) used for communicating between the panel and the window manager for instance. It is about as

simple as it gets, passing messages via X Atoms. For this reason it is limited in the size and complexity of the data that can be passed (X atoms must be small to remain efficient) and it also makes it so that X is required. CORBA was thought to be a more effective IPC/RPC solution. However, after a year of attempting to make heavy use of CORBA in KDE, we have realized that it is a bit slow and memory intensive for simple use. It also has no authentication available.

What we really needed was an extremely simple protocol with basic authorization, along the lines of MIT-MAGIC-COOKIE, as used by X. It would not be able to do NEARLY what CORBA was able to do, but for the simple tasks required it would be sufficient. Some examples of such tasks might be an application sending a message to the panel saying, "I have started, stop displaying the 'application starting' wait state," or having a new application that starts query to see if any other applications of the same name are running. If they are, simply call a function on the remote application to create a new window, rather than starting a new process.

Implementation:

DCOP is a simple IPC/RPC mechanism built to operate over sockets. Either unix domain sockets or tcp/ip sockets are supported. DCOP is built on top of the Inter Client Exchange (ICE) protocol, which comes standard as a part of X11R6 and later. It also depends on Qt, but beyond that it does not require any other libraries. Because of this, it is extremely lightweight, enabling it to be linked into all KDE applications with low overhead.

Model:

The model is simple. Each application using DCOP is a client. They communicate to each other through a DCOP server, which functions like a traffic director, dispatching messages/calls to the proper destinations. All clients are peers of each other.

Two types of actions are possible with DCOP: "send and forget" messages, which do not block, and "calls," which block waiting for some data to be returned.

Any data that will be sent is serialized (marshalled, for you CORBA types) using the built-in QDataStream operators available in all of the Qt classes. This is fast and easy. In fact it's so little work that you can easily write the marshalling code by hand. In addition, there's a simple IDL-like compiler available (dcopidl and dcopidl2cpp) that generates stubs and skeletons for you. Using the dcopidl compiler has the additional benefit of type safety.

This HOWTO describes the manual method first and covers the dcopidl compiler later.

Establishing the Connection:

KApplication has gained a method called "KApplication::dcopClient()" which returns a pointer to a DCOPClient instance. The first time this method is called, the client class will be created. DCOPClients have unique identifiers attached to them which are based on what KApplication::name() returns. In fact, if there is only a single instance of the program running, the appId will be equal to KApplication::name().

To actually enable DCOP communication to begin, you must use DCOPClient::attach(). This will attempt to attach to the DCOP server. If no server is found or there is any other type of error, attach() will return false. KApplication will catch a dcop signal and display an appropriate error message box in that case.

After connecting with the server via DCOPClient::attach(), you need to register this appId with the server so it knows about you. Otherwise, you are communicating anonymously. Use the DCOPClient::registerAs(const QString &name) to do so. In the simple case:

```
/*
 * returns the appId that is actually registered, which _may_ be
 * different from what you passed
 */
appId = client->registerAs(kApp->name());
```

If you never retrieve the DCOPClient pointer from KApplication, the object will not be created and thus there will be no memory overhead.

You may also detach from the server by calling DCOPClient::detach(). If you wish to attach again you will need to re-register as well. If you only wish to change the ID under which you are registered, simply call DCOPClient::registerAs() with the new name.

KUniqueApplication automatically registers itself to DCOP. If you are using KUniqueApplication you should not attach or register yourself, this is already done. The appId is by definition equal to kapp->name(). You can retrieve the registered DCOP client by calling kapp->dcopClient().

Sending Data to a Remote Application:

To actually communicate, you have one of two choices. You may either call the "send" or the "call" method. Both methods require three identification parameters: an application identifier, a remote object,

a remote function. Sending is asynchronous (i.e. it returns immediately) and may or may not result in your own application being sent a message at some point in the future. Then "send" requires one and "call" requires two data parameters.

The remote object must be specified as an object hierarchy. That is, if the toplevel object is called "fooObject" and has the child "barObject", you would reference this object as "fooObject/barObject". Functions must be described by a full function signature. If the remote function is called "doIt", and it takes an int, it would be described as "doIt(int)". Please note that the return type is not specified here, as it is not part of the function signature (or at least the C++ understanding of a function signature). You will get the return type of a function back as an extra parameter to `DCOPClient::call()`. See the section on `call()` for more details.

In order to actually get the data to the remote client, it must be "serialized" via a `QDataStream` operating on a `QByteArray`. This is how the data parameter is "built". A few examples will make clear how this works.

Say you want to call "doIt" as described above, and not block (or wait for a response). You will not receive the return value of the remotely called function, but you will not hang while the RPC is processed either. The return value of `send()` indicates whether DCOP communication succeeded or not.

```
QByteArray data;
QDataStream arg(data, IO_WriteOnly);
arg << 5;
if (!client->send("someAppId", "fooObject/barObject", "doIt(int)",
                data))
    qDebug("there was some error using DCOP.");
```

OK, now let's say we wanted to get the data back from the remotely called function. You have to execute a `call()` instead of a `send()`. The returned value will then be available in the data parameter "reply". The actual return value of `call()` is still whether or not DCOP communication was successful.

```
QByteArray data, replyData;
QString replyType;
QDataStream arg(data, IO_WriteOnly);
arg << 5;
if (!client->call("someAppId", "fooObject/barObject", "doIt(int)",
                data, replyType, replyData))
```

```

    qDebug("there was some error using DCOP.");
else {
    QDataStream reply(replyData, IO_ReadOnly);
    if (replyType == "QString") {
        QString result;
        reply >> result;
        print("the result is: %s",result.latin1());
    } else
        qDebug("doIt returned an unexpected type of reply!");
}
}

```

N.B.: You cannot call() a method belonging to an application which has registered with an unique numeric id appended to its textual name (see dcopclient.h for more info). In this case, DCOP would not know which application it should connect with to call the method. This is not an issue with send(), as you can broadcast to all applications that have registered with appname-<numeric_id> by using a wildcard (e.g. 'konsole-*'), which will send your signal to all applications called 'konsole'.

Receiving Data via DCOP:

Currently the only real way to receive data from DCOP is to multiply inherit from the normal class that you are inheriting (usually some sort of QWidget subclass or QObject) as well as the DCOPObject class. DCOPObject provides one very important method: DCOPObject::process(). This is a pure virtual method that you must implement in order to process DCOP messages that you receive. It takes a function signature, QByteArray of parameters, and a reference to a QByteArray for the reply data that you must fill in.

Think of DCOPObject::process() as a sort of dispatch agent. In the future, there will probably be a precompiler for your sources to write this method for you. However, until that point you need to examine the incoming function signature and take action accordingly. Here is an example implementation.

```

bool BarObject::process(const QString &fun, const QByteArray &data,
                        QString &replyType, QByteArray &replyData)
{
    if (fun == "doIt(int)") {
        QDataStream arg(data, IO_ReadOnly);
        int i; // parameter
        arg >> i;
        QString result = self->doIt (i);
        QDataStream reply(replyData, IO_WriteOnly);
        reply << result;
        replyType = "QString";
        return true;
    }
}

```

```

    } else {
        qDebug("unknown function call to BarObject::process()");
        return false;
    }
}

```

Receiving Calls and processing them:

If your applications is able to process incoming function calls right away the above code is all you need. When your application needs to do more complex tasks you might want to do the processing out of 'process' function call and send the result back later when it becomes available.

For this you can ask your DCOPClient for a transactionId. You can then return from the 'process' function and when the result is available finish the transaction. In the mean time your application can receive incoming DCOP function calls from other clients.

Such code could like this:

```

bool BarObject::process(const QString &fun, const QByteArray &data,
                       QString &, QByteArray &)
{
    if (fun == "doIt(int)") {
        QDataStream arg(data, IO_ReadOnly);
        int i; // parameter
        arg >> i;
        QString result = self->doIt(i);

        DCOPClientTransaction *myTransaction;
        myTransaction = kapp->dcopClient()->beginTransaction();

        // start processing...
        // Calls slotProcessingDone when finished.
        startProcessing( myTransaction, i);

        return true;
    } else {
        qDebug("unknown function call to BarObject::process()");
        return false;
    }
}

```

```

slotProcessingDone(DCOPClientTransaction *myTransaction, const QString
&result)
{
    QString replyType = "QString";
    QByteArray replyData;
    QDataStream reply(replyData, IO_WriteOnly);
    reply << result;
}

```

```
    kapp->dcopClient()->endTransaction( myTransaction, replyType,  
replyData );  
}
```

DCOP Signals

Sometimes a component wants to send notifications via DCOP to other components but does not know which components will be interested in these notifications. One could use a broadcast in such a case but this is a very crude method. For a more sophisticated method DCOP signals have been invented.

DCOP signals are very similar to Qt signals, there are some differences though. A DCOP signal can be connected to a DCOP function. Whenever the DCOP signal gets emitted, the DCOP functions to which the signal is connected are being called. DCOP signals are, just like Qt signals, one way. They do not provide a return value.

A DCOP signal originates from a DCOP Object/DCOP Client combination (sender). It can be connected to a function of another DCOP Object/DCOP Client combination (receiver).

There are two major differences between connections of Qt signals and connections of DCOP signals. In DCOP, unlike Qt, a signal connections can have an anonymous sender and, unlike Qt, a DCOP signal connection can be non-volatile.

With DCOP one can connect a signal without specifying the sending DCOP Object or DCOP Client. In that case signals from any DCOP Object and/or DCOP Client will be delivered. This allows the specification of certain events without tying oneself to a certain object that implements the events.

Another DCOP feature are so called non-volatile connections. With Qt signal connections, the connection gets deleted when either sender or receiver of the signal gets deleted. A volatile DCOP signal connection will behave the

same. However, a non-volatile DCOP signal connection will not get deleted when the sending object gets deleted. Once a new object gets created with the same name as the original sending object, the connection will be restored. There is no difference between the two when the receiving object gets deleted, in that case the signal connection will always be deleted.

A receiver can create a non-volatile connection while the sender doesn't (yet) exist. An anonymous DCOP connection should always be non-volatile.

The following example shows how KLauncher emits a signal whenever it notices that an application that was started via KLauncher terminates.

```
QByteArray params;
QDataStream stream(params, IO_WriteOnly);
stream << pid;
kapp->dcopClient()->emitDCOPSignal("clientDied(pid_t)", params);
```

The task manager of the KDE panel connects to this signal. It uses an anonymous connection (it doesn't require that the signal is being emitted by KLauncher) that is non-volatile:

```
connectDCOPSignal(0, 0, "clientDied(pid_t)", "clientDied(pid_t)",
false);
```

It connects the clientDied(pid_t) signal to its own clientDied(pid_t) DCOP function. In this case the signal and the function to call have the same name. This isn't needed as long as the arguments of both signal and receiving function match. The receiving function may ignore one or more of the trailing arguments of the signal. E.g. it is allowed to connect the clientDied(pid_t) signal to a clientDied(void) DCOP function.

Using the dcopidl compiler

dcopidl makes setting up a DCOP server easy. Instead of having to implement the process() method and unmarshalling (retrieving from QByteArray) parameters manually, you can let dcopidl create the necessary code on your behalf.

This also allows you to describe the interface for your class in a single, separate header file.

Writing an IDL file is very similar to writing a normal C++ header. An exception is the keyword 'ASYNC'. It indicates that a call to this function shall be processed asynchronously. For the C++ compiler, it expands to 'void'.

Example:

```
#ifndef MY_INTERFACE_H
#define MY_INTERFACE_H

#include <dcopobject.h>

class MyInterface : virtual public DCOPObject
{
    K_DCOP

    k_dcop:

        virtual ASYNC myAsynchronousMethod(QString someParameter) = 0;
        virtual QRect mySynchronousMethod() = 0;
};

#endif
```

As you can see, you're essentially declaring an abstract base class, which virtually inherits from DCOPObject.

If you're using the standard KDE build scripts, then you can simply add this file (which you would call MyInterface.h) to your sources directory. Then you edit your Makefile.am, adding 'MyInterface.skel' to your SOURCES list and MyInterface.h to include_HEADERS.

The build scripts will use dcopidl to parse MyInterface.h, converting it to an XML description in MyInterface.kidl. Next, a file called MyInterface_skel.cpp will automatically be created, compiled and linked with your binary.

The next thing you have to do is to choose which of your classes will implement the interface described in MyInterface.h. Alter the inheritance of this class such that it virtually inherits from MyInterface. Then add declarations to your class interface similar to those on MyInterface.h, but virtual, not pure virtual.

Example:

```

class MyClass: public QObject, virtual public MyInterface
{
    Q_OBJECT

public:
    MyClass();
    ~MyClass();

    ASYNC myAsynchronousMethod(QString someParameter);
    QRect mySynchronousMethod();
};

```

Note: (Qt issue) Remember that if you are inheriting from QObject, you must place it first in the list of inherited classes.

In the implementation of your class' ctor, you must explicitly initialize those classes from which you are inheriting from. This is, of course, good practise, but it is essential here as you need to tell DCOPObject the name of the interface which your are implementing.

Example:

```

MyClass::MyClass()
    : QObject(),
      DCOPObject("MyInterface")
{
    // whatever...
}

```

Now you can simply implement the methods you have declared in your interface, exactly the same as you would normally.

Example:

```

void MyClass::myAsynchronousMethod(QString someParameter)
{
    qDebug("myAsyncMethod called with param ` " + someParameter + "`");
}

```

It is not necessary (though very clean) to define an interface as an abstract class of its own, like we did in the example above. We could just as well have defined a k_dcop section directly within MyClass:

```

class MyClass: public QObject, virtual public DCOPObject
{
    Q_OBJECT

```

```

K_DCOP

public:
    MyClass();
    ~MyClass();

    k_dcop:
        ASYNC myAsynchronousMethod(QString someParameter);
        QRECT mySynchronousMethod();
};

```

In addition to skeletons, `dcopidl2cpp` also generate stubs. Those make it easy to call a DCOP interface without doing the marshalling manually. To use a stub, add `MyInterface.stub` to the `SOURCES` list of your `Makefile.am`. The stub class will then be called `MyInterface_stub`.

Conclusion:

Hopefully this document will get you well on your way into the world of inter-process communication with KDE! Please direct all comments and/or suggestions to Preston Brown <pbrown@kde.org> and Matthias Ettrich <ettrich@kde.org>.

Inter-user communication

Sometimes it might be interesting to use DCOP between processes belonging to different users, e.g. a frontend process running with the user's id, and a backend process running as root.

To do this, two steps have to be taken:

- a) both processes need to talk to the same DCOP server
- b) the authentication must be ensured

For the first step, you simply pass the server address (as found in `.DCOPserver`) to the second process. For the authentication, you can use the `ICEAUTHORITY` environment variable to tell the second process where to find the authentication information. (Note that this implies that the second process is able to read the authentication file, so it will probably only work if the second process runs as root. If it should run as another user, a similar approach to what `kdesu` does with `xauth` must be taken. In fact, it would be a very good idea to add DCOP support to `kdesu`!)

For example

```

ICEAUTHORITY=~user/.ICEauthority kdesu root -c kcmroot -dcopserver
`cat ~user/.DCOPserver`

```

will, after kdesu got the root password, execute kcmroot as root, talking to the user's dcop server.

NOTE: DCOP communication is not encrypted, so please do not pass important information around this way.

Performance Tests:

A few back-of-the-napkin tests folks:

Code:

```
#include <kapplication.h>

int main(int argc, char **argv)
{
    KApplication *app;

    app = new KApplication(argc, argv, "testit");
    return app->exec();
}
```

Compiled with:

```
g++ -O2 -o testit testit.cpp -I$QTDIR/include -L$QTDIR/lib -lkdecore
```

on Linux yields the following memory use statistics:

```
VmSize:      8076 kB
VmLck:        0 kB
VmRSS:       4532 kB
VmData:      208 kB
VmStk:       20 kB
VmExe:        4 kB
VmLib:      6588 kB
```

If I create the KApplication's DCOPClient, and call attach() and registerAs(), it changes to this:

```
VmSize:      8080 kB
VmLck:        0 kB
VmRSS:       4624 kB
VmData:      208 kB
VmStk:       20 kB
VmExe:        4 kB
VmLib:      6588 kB
```

Basically it appears that using DCOP causes 100k more memory to be

resident, but no more data or stack. So this will be shared between all processes, right? 100k to enable DCOP in all apps doesn't seem bad at all. :)

OK now for some timings. Just creating a KApplication and then exiting (i.e. removing the call to KApplication::exec) takes this much time:

```
0.28user 0.02system 0:00.32elapsed 92%CPU (0avgtext+0avgdata
0maxresident)k
0inputs+0outputs (1084major+62minor)pagefaults 0swaps
```

I.e. about 1/3 of a second on my PII-233. Now, if we create our DCOP object and attach to the server, it takes this long:

```
0.27user 0.03system 0:00.34elapsed 87%CPU (0avgtext+0avgdata
0maxresident)k
0inputs+0outputs (1107major+65minor)pagefaults 0swaps
```

I.e. about 1/3 of a second. Basically DCOPClient creation and attaching gets lost in the statistical variation ("noise"). I was getting times between .32 and .48 over several runs for both of the example programs, so obviously system load is more relevant than the extra two calls to DCOPClient::attach and DCOPClient::registerAs, as well as the actual DCOPClient constructor time.

Usage: depcomp [--help] [--version] PROGRAM [ARGS]

Run PROGRAMS ARGS to compile a file, generating dependencies
as side-effects.

Environment variables:
depmode      Dependency tracking mode.
source       Source file read by 'PROGRAMS ARGS'.
object       Object file output by 'PROGRAMS ARGS'.
DEPDIR       directory where to store dependencies.
depfile      Dependency file to output.
tmpdepfile   Temporary file to use when outputting dependencies.
libtool      Whether libtool is used (yes/no).

Report bugs to <bug-automake@gnu.org>.

## Note that this doesn't just cater to obsosete pre-3.x GCC
## compilers.
## but also to in-use compilers like IMB xlc/xlC and the HP C
## compiler.
## (see the conditional assignment to $gccflag above).
## There are various ways to get dependency output from gcc. Here's
## why we pick this rather obscure method:
## - Don't want to use -MD because we'd like the dependencies to end
##   up in a subdir. Having to rename by hand is ugly.
##   (We might end up doing this anyway to support other compilers.)
## - The DEPENDENCIES_OUTPUT environment variable makes gcc act like
##   -MM, not -M (despite what the docs say). Also, it might not be
##   supported by the other compilers which use the 'gcc' depmode.
## - Using -M directly means running the compiler twice (even worse
##   than renaming).
    if test -z "$gccflag"; then

gcc)
## Note that this doesn't just cater to obsosete pre-3.x GCC
## compilers.
## but also to in-use compilers like IMB xlc/xlC and the HP C
## compiler.
## (see the conditional assignment to $gccflag above).
## There are various ways to get dependency output from gcc. Here's
## why we pick this rather obscure method:
## - Don't want to use -MD because we'd like the dependencies to end
##   up in a subdir. Having to rename by hand is ugly.
##   (We might end up doing this anyway to support other compilers.)
## - The DEPENDENCIES_OUTPUT environment variable makes gcc act like
##   -MM, not -M (despite what the docs say). Also, it might not be
##   supported by the other compilers which use the 'gcc' depmode.
## - Using -M directly means running the compiler twice (even worse
##   than renaming).
  if test -z "$gccflag"; then

icc)
# Intel's C compiler anf tcc (Tiny C Compiler) understand '-MD -MF
file'.
# However on
#   $CC -MD -MF foo.d -c -o sub/foo.o sub/foo.c
# ICC 7.0 will fill foo.d with something like
#   foo.o: sub/foo.c
#   foo.o: sub/foo.h
# which is wrong. We want
#   sub/foo.o: sub/foo.c
#   sub/foo.o: sub/foo.h
#   sub/foo.c:
#   sub/foo.h:
# ICC 7.1 will output
#   foo.o: sub/foo.c sub/foo.h
# and will wrap long lines using '\':
#   foo.o: sub/foo.c ... \
#   sub/foo.h ... \
#   ...
# tcc 0.9.26 (FIXME still under development at the moment of
writing)
# will emit a similar output, but also prepend the continuation
lines
# with horizontal tabulation characters.

```

The order of this option in the case statement is important, since the ## shell code in configure will try each of these formats in the order ## listed in this file. A plain '-MD' option would be understood by many ## compilers, so we must ensure this comes after the gcc and icc options.

pgcc)

```

# Portland's C compiler understands '-MD'.
# Will always output deps to 'file.d' where file is the root name of
the
# source file under compilation, even if file resides in a
subdirectory.
# The object file name does not affect the name of the '.d' file.
# pgcc 10.2 will output
#   foo.o: sub/foo.c sub/foo.h
# and will wrap long lines using '\' :
#   foo.o: sub/foo.c ... \
#     sub/foo.h ... \
#     ...
dir=`echo "$object" | sed -e 's|/[^/]*$|/|'`

File = HACKING

The mainline git tree for this code is at
[git://anongit.freedesktop.org/git/dbus/dbus-glib](https://anongit.freedesktop.org/git/dbus/dbus-glib).

= Creating changes =

Be sure to match the existing code style (Emacs: "gnu").

If you are making major changes which you wish to be incorporated upstream,
please do as small commits to your local git tree, so there is a good history of your changes.

When you consider changes ready for merging to mainline, use "git-format-patch" or otherwise generate diffs. Post those diffs

to a new bug at <http://bugs.freedesktop.org>, project DBus, component GLib.

For nontrivial changes *please* try to extend the test suite to cover it. The test infrastructure is in test/core/, and currently there are a lot of tests in the single file test/core/test-dbus-glib.c. Extending this file is suggested (in the future we would like to break this file up).

Run "make check" to run the test suite.

= Committing =

If applying a patch from someone else that created them via "git-format-patch", you can use "git-am -s" to apply. Otherwise apply the patch and then use "git commit --author ..."

Regardless:

== Nontrivial changes ==

Nontrivial patches should always go through Bugzilla for peer review, so you should have a bug number. The commit should be of the form:

Bug XXXXXX: Single line summary here

- * dbus/filename.c: Why I changed this.
- * dbus/otherfile.c: Why I changed this.

== Trivial changes ==

Just use a single line summary, like:

Fix typo in NEWS

= Making a release =

DBus-Glib now uses an even-stable odd-development release numbering system. The current number in configure.ac should be odd.

To make a release (please replace use of 0.76 with the new version)

- * make
- * make distcheck
- * edit configure.ac, change version to even (e.g. 0.75 -> 0.76)
- * also in configure.ac, update LT_CURRENT, LT_REVISION and LT_AGE
- * ./autogen.sh
- * make
- * make distcheck
- * sign the tarball (or use: make dbus-glib-0.76.tar.gz.asc)
- * make maintainer-upload-release

```
* git commit -m "Release"
* git tag -a dbus-glib_0.76
* edit configure.ac, change version to odd (e.g. 0.76 -> 0.77)
* git commit -m "Bump version for development"
* Update the wiki:
http://www.freedesktop.org/wiki/Software/DBusBindings
* Announce the release on the mailing list, summarizing notable
changes.
```

NEWS is unmaintained.

File = HACKING.~1~

The guidelines in this file are the ideals; it's better to send a not-fully-following-guidelines patch than no patch at all, though. We can always polish it up.

Mailing list

===

The D-Bus mailing list is dbus@lists.freedesktop.org; discussion of patches, etc. should go there.

Security

===

Most of D-Bus is security sensitive. Guidelines related to that:

- avoid `memcpy()`, `sprintf()`, `strlen()`, `snprintf`, `strlcat()`, `strstr()`, `strtok()`, or any of this stuff. Use `DBusString`. If `DBusString` doesn't have the feature you need, add it to `DBusString`.

There are some exceptions, for example if your strings are just used to index a hash table and you don't do any parsing/modification of them, perhaps `DBusString` is wasteful and wouldn't help much. But definitely if you're doing any parsing, reallocation, etc. use `DBusString`.

- do not include system headers outside of `dbus-memory.c`, `dbus-sysdeps.c`, and other places where they are already included. This gives us one place to audit all external dependencies on features in `libc`, etc.
- do not use `libc` features that are "complicated" and may contain security holes. For example, you probably shouldn't try to use `regcomp()` to compile an untrusted regular expression. Regular expressions are just too complicated, and there are many different `libc`'s out there.

- we need to design the message bus daemon (and any similar features) to use limited privileges, run in a chroot jail, and so on.

<http://vsftpd.beasts.org/> has other good security suggestions.

Coding Style

===

- The C library uses GNU coding conventions, with GLib-like extensions (e.g. lining up function arguments). The Qt wrapper uses KDE coding conventions.
- Write docs for all non-static functions and structs and so on. try "doxygen Doxyfile" prior to commit and be sure there are no warnings printed.
- All external interfaces (network protocols, file formats, etc.) should have documented specifications sufficient to allow an alternative implementation to be written. Our implementation should be strict about specification compliance (should not for example heuristically parse a file and accept not-well-formed data). Avoiding heuristics is also important for security reasons; if it looks funny, ignore it (or exit, or disconnect).

Development

===

D-Bus uses Git as its version control system. The main repository is hosted at git.freedesktop.org/dbus/dbus. To clone D-Bus, execute the following command:

```
git clone git://git.freedesktop.org/dbus/dbus
```

OR

```
git clone git.freedesktop.org:dbus/dbus
```

The latter form is the one that allows pushing, but it also requires an SSH account on the server. The former form allows anonymous checkouts.

D-Bus development happens in two branches in parallel: the current stable branch, with an even minor number (like 1.0, 1.2 and 1.4), and the next development branch, with the next odd number.

The stable branch is named after the version number itself (dbus-1.2, dbus-1.4), whereas the development branch is simply known as "master".

When making a change to D-Bus, do the following:

- check out the earliest branch of D-Bus that makes sense to have your change in. If it's a bugfix, it's normally the current stable branch; if it's a feature, it's normally the "master" branch. If you have an important security fix, you may want to apply to older

branches too.

- for large changes:
 - if you're developing a new, large feature, it's recommended to create a new branch and do your development there. Publish your branch at a suitable place and ask others to help you develop and test it. Once your feature is considered finalised, you may merge it into the "master" branch.
- for small changes:
 - . make your change to the source code
 - . execute tests to guarantee that you're not introducing a regression. For that, execute: `make check` (if possible, add a new test to check the fix you're introducing)
 - . commit your change using `"git commit"` in the commit message, write a short sentence describing what you did in the first line. Then write a longer description in the next paragraph(s).
 - . repeat the previous steps if necessary to have multiple commits
- extract your patches and send to the D-Bus mailing list for review or post them to the D-Bus Bugzilla, attaching them to a bug report. To extract the patches, execute:
`git format-patch origin/master`
- once your code has been reviewed, you may push it to the Git server:
 - `git push origin my-branch:remote`
 - OR
 - `git push origin dbus-X.Y`
 - OR
 - `git push origin master`
 - (consult the Git manual to know which command applies)
- (Optional) if you've not worked on "master", merge your changes to that branch. If you've worked on an earlier branch than the current stable, merge your changes upwards towards the stable branch, then from there into "master".
 - . execute: `git checkout master`
 - . ensure that you have the latest "master" from the server, update if you don't
 - . execute: `git merge dbus-X.Y`
 - . if you have any conflicts, resolve them, `git add` the conflicted files and then `git commit`
 - . push the "master" branch to the server as well

Executing this merge is recommended, but not necessary for all changes. You should do this step if your bugfix is critical for the development in "master", or if you suspect that conflicts will arise (you're usually the best person to resolve conflicts introduced by

your own code), or if it has been too long since the last merge.

Making a release

===

To make a release of D-Bus, do the following:

- check out a fresh copy from Git
- verify that the libtool versioning/library soname is changed if it needs to be, or not changed if not
- update the file NEWS based on the git history
- verify that the version number of dbus-specification.xml is changed if it needs to be; if changes have been made, update the release date in that file
- update the AUTHORS file with "make update-authors" if necessary
- the version number should have major.minor.micro, even if micro is 0, i.e. "1.0.0" and "1.2.0" not "1.0"/"1.2"; the micro version should be even for releases, and odd for intermediate snapshots
- "make distcheck" (DO NOT just "make dist" - pass the check!)
- if make distcheck fails, fix it.
- once distcheck succeeds, "git commit -a". This is the version of the tree that corresponds exactly to the released tarball.
- tag the tree with "git tag -s -m 'Released X.Y.Z' dbus-X.Y.Z" where X.Y.Z is the version of the release. If you can't sign then simply created an unsigned annotated tag:
"git tag -a -m 'Released X.Y.Z' dbus-X.Y.Z".
- bump the version number up in configure.ac (so the micro version is odd),
and commit it. Make sure you do this *after* tagging the previous release! The idea is that git has a newer version number than anything released. Similarly, bump the version number of dbus-specification.xml and set the release date to "(not finalized)".
- merge the branch you've released to the chronologically-later branch (usually "master"). You'll probably have to fix a merge conflict in configure.ac (the version number).
- push your changes and the tag to the central repository with
git push origin master dbus-X.Y dbus-X.Y.Z

- scp your tarball to freedesktop.org server and copy it to
`dbus.freedesktop.org:/srv/dbus.freedesktop.org/www/releases/dbus/dbus-X.Y.Z.tar.gz`.
This should be possible if you're in group "dbus"
- Update the online documentation with ``make -C doc maintainer-upload-docs``.
- update the wiki page <http://www.freedesktop.org/Software/dbus> by adding the new release under the Download heading. Then, cut the link and changelog for the previous that was there.
- update the wiki page <http://www.freedesktop.org/Software/DbusReleaseArchive> pasting the previous release. Note that bullet points for each of the changelog items must be indented three more spaces to conform to the formatting of the other releases there.
- post to `dbus@lists.freedesktop.org` announcing the release.

Making a ".0" stable release

===

We create a branch for each stable release. The branch name should be `dbus-X.Y` which is a branch that has releases versioned `X.Y.Z`; changes on a stable branch should be limited to significant bug fixes.

Because we won't make minor changes like keeping up with the latest deprecations on a stable branch, stable branches should turn off the gcc warning for deprecated declarations (e.g. see commit `4ebb275ab7`).

Be extra-careful not to merge master (or any branch based on master) into a stable branch.

To branch:

```
git branch dbus-X.Y
```

and upload the branch tag to the server:

```
git push origin dbus-X.Y
```

To develop in this branch:

```
git checkout dbus-X.Y
```

Environment variables

===

These are the environment variables that are used by the D-Bus client library

DBUS_VERBOSE=1

Turns on printing verbose messages. This only works if D-Bus has been compiled with `--enable-verbose-mode`

DBUS_MALLOC_FAIL_NTH=n

Can be set to a number, causing every nth call to `dbus_alloc` or `dbus_realloc` to fail. This only works if D-Bus has been compiled with `--enable-tests`.

DBUS_MALLOC_FAIL_GREATER_THAN=n

Can be set to a number, causing every call to `dbus_alloc` or `dbus_realloc` to fail if the number of bytes to be allocated is greater than the specified number. This only works if D-Bus has been compiled with `--enable-tests`.

DBUS_TEST_MALLOC_FAILURES=n

Many of the D-Bus tests will run over and over, once for each malloc involved in the test. Each run will fail a different malloc, plus some number of mallocs following that malloc (because a fair number of bugs only happen if two or more mallocs fail in a row, e.g. error recovery that itself involves malloc). This env variable sets the number of mallocs to fail.

Here's why you care: If set to 0, then the malloc checking is skipped, which makes the test suite a heck of a lot faster. Just run with this env variable unset before you commit.

Tests

===

These are the test programs that are built if dbus is compiled using `--enable-tests`.

dbus/dbus-test

This is the main unit test program that tests all aspects of the D-Bus client library.

dbus/bus-test

This is the unit test program for the message bus.

test/break-loader

A test that tries to break the message loader by passing it randomly created invalid messages.

test/name-test/*

This is a suite of programs which are run with a temporary session bus.

If your test involves multiple processes communicating, your best bet is to add a test in here.

"make check" runs all the deterministic test programs (i.e. not break-loader).

"make lcov-check" is available if you configure with --enable-compiler-coverage and gives a complete report on test suite coverage.

Patches

===

Please file them at <http://bugzilla.freedesktop.org> under component dbus, and also post to the mailing list for discussion. The commit rules are:

- for fixes that don't affect API or protocol, they can be committed if any one qualified reviewer other than patch author reviews and approves
- for fixes that do affect API or protocol, two people in the reviewer group have to review and approve the commit, and posting to the list is definitely mandatory
- if there's a live unresolved controversy about a change, don't commit it while the argument is still raging.
- at their discretion, members of the reviewer group may also commit branches/patches under these conditions:
 - the branch does not add or change API, ABI or wire-protocol
 - the branch solves a known problem and is covered by the regression tests
 - there are no objections from the rest of the review group within a week of the patches being attached to Bugzilla
 - the committer gets a positive review on Bugzilla from someone they consider qualified to review the change (e.g. a colleague with D-Bus experience; not necessarily a member of the reviewer group)
- regardless of reviews, to commit a patch:
 - make check must pass
 - the test suite must be extended to cover the new code as much as reasonably feasible (see Tests above)
 - the patch has to follow the portability, security, and style guidelines
 - the patch should as much as reasonable do one thing, not many unrelated changesNo reviewer should approve a patch without these attributes, and failure on these points is grounds for reverting the patch.

The reviewer group that can approve patches:

Havoc Pennington <hp@pobox.net>
Michael Meeks <michael.meeks@novell.com>

File = INSTALL

```
DBus GLib Installation
=====
```

```
Quick start
=====
```

DBus uses GNU AutoTools for its build system, thus the basic install procedure can be summarized as:

```
./configure --prefix=/usr
make
su make install
```

The configure script will automatically determine whether to try and build bindings for GLib, Qt, Qt3, Python and Mono based on what tools are installed on the host system. The default build behaviour can be overridden using the --enable-XXX/--disable-XXX arguments to configure.

A typical scenario in which it is desirable to override automatic detection, is during packaging of binary builds, where a predictable dependancy chain is required. For more details on GNU AutoTools installation, consult the generic instructions later in this document

```
External software dependancies
=====
```

Requisite:

- GLib >= 2.6

Optional:

- gtk-doc (for API documentation)

=====

The rest of this document contains the generic GNU AutoTools install instructions....

Basic Installation

=====

These are generic installation instructions.

The ``configure'` shell script attempts to guess correct values for various system-dependent variables used during compilation. It uses those values to create a ``Makefile'` in each directory of the package. It may also create one or more ``.h'` files containing system-dependent definitions. Finally, it creates a shell script ``config.status'` that you can run in the future to recreate the current configuration, a file

``config.cache'` that saves the results of its tests to speed up reconfiguring, and a file ``config.log'` containing compiler output (useful mainly for debugging ``configure'`).

If you need to do unusual things to compile the package, please try to figure out how ``configure'` could check whether to do them, and mail diffs or instructions to the address given in the ``README'` so they can be considered for the next release. If at some point ``config.cache'` contains results you don't want to keep, you may remove or edit it.

The file ``configure.in'` is used to create ``configure'` by a program called ``autoconf'`. You only need ``configure.in'` if you want to change it or regenerate ``configure'` using a newer version of ``autoconf'`.

The simplest way to compile this package is:

1. ``cd'` to the directory containing the package's source code and type

``../configure'` to configure the package for your system. If you're

using ``csh'` on an old version of System V, you might need to type ``sh ./configure'` instead to prevent ``csh'` from trying to execute ``configure'` itself.

Running ``configure'` takes awhile. While running, it prints some messages telling which features it is checking for.

2. Type ``make'` to compile the package.

3. Optionally, type ``make check'` to run any self-tests that come with the package.
4. Type ``make install'` to install the programs and any data files and documentation.
5. You can remove the program binaries and object files from the source code directory by typing ``make clean'`. To also remove the files that ``configure'` created (so you can compile the package for a different kind of computer), type ``make distclean'`. There is also a ``make maintainer-clean'` target, but that is intended mainly for the package's developers. If you use it, you may have to get all sorts of other programs in order to regenerate files that came with the distribution.

Compilers and Options =====

Some systems require unusual options for compilation or linking that the ``configure'` script does not know about. You can give ``configure'` initial values for variables by setting them in the environment. Using a Bourne-compatible shell, you can do that on the command line like this:

```
CC=c89 CFLAGS=-O2 LIBS=-lposix ./configure
```

Or on systems that have the ``env'` program, you can do it like this:

```
env CPPFLAGS=-I/usr/local/include LDFLAGS=-s ./configure
```

Compiling For Multiple Architectures =====

You can compile the package for more than one kind of computer at the same time, by placing the object files for each architecture in their own directory. To do this, you must use a version of ``make'` that supports the ``VPATH'` variable, such as GNU ``make'`. ``cd'` to the directory where you want the object files and executables to go and run the ``configure'` script. ``configure'` automatically checks for the source code in the directory that ``configure'` is in and in ``..'.`

If you have to use a ``make'` that does not support the ``VPATH'` variable, you have to compile the package for one architecture at a time

in the source code directory. After you have installed the package for one architecture, use ``make distclean'` before reconfiguring for another architecture.

Installation Names =====

By default, ``make install'` will install the package's files in ``/usr/local/bin'`, ``/usr/local/man'`, etc. You can specify an installation prefix other than ``/usr/local'` by giving ``configure'` the option ``--prefix=PATH'`.

You can specify separate installation prefixes for architecture-specific files and architecture-independent files. If you give ``configure'` the option ``--exec-prefix=PATH'`, the package will use `PATH` as the prefix for installing programs and libraries. Documentation and other data files will still use the regular prefix.

In addition, if you use an unusual directory layout you can give options like ``--bindir=PATH'` to specify different values for particular kinds of files. Run ``configure --help'` for a list of the directories you can set and what kinds of files go in them.

If the package supports it, you can cause programs to be installed with an extra prefix or suffix on their names by giving ``configure'` the option ``--program-prefix=PREFIX'` or ``--program-suffix=SUFFIX'`.

Optional Features =====

Some packages pay attention to ``--enable-FEATURE'` options to ``configure'`, where `FEATURE` indicates an optional part of the package. They may also pay attention to ``--with-PACKAGE'` options, where `PACKAGE` is something like ``gnu-as'` or ``x'` (for the X Window System). The ``README'` should mention any ``--enable-'` and ``--with-'` options that the package recognizes.

For packages that use the X Window System, ``configure'` can usually find the X include and library files automatically, but if it doesn't, you can use the ``configure'` options ``--x-includes=DIR'` and ``--x-libraries=DIR'` to specify their locations.

Specifying the System Type =====

There may be some features ``configure'` can not figure out automatically, but needs to determine by the type of host the package

will run on. Usually `configure` can figure that out, but if it prints a message saying it can not guess the host type, give it the `--host=TYPE` option. TYPE can either be a short name for the system type, such as `sun4`, or a canonical name with three fields:
CPU-COMPANY-SYSTEM

See the file `config.sub` for the possible values of each field. If `config.sub` isn't included in this package, then this package doesn't need to know the host type.

If you are building compiler tools for cross-compiling, you can also use the `--target=TYPE` option to select the type of system they will produce code for and the `--build=TYPE` option to select the type of system on which you are compiling the package.

Sharing Defaults

=====

If you want to set default values for `configure` scripts to share, you can create a site shell script called `config.site` that gives default values for variables like `CC`, `cache_file`, and `prefix`. `configure` looks for `PREFIX/share/config.site` if it exists, then `PREFIX/etc/config.site` if it exists. Or, you can set the `CONFIG_SITE` environment variable to the location of the site script. A warning: not all `configure` scripts look for a site script.

Operation Controls

=====

`configure` recognizes the following options to control how it operates.

`--cache-file=FILE`

Use and save the results of the tests in FILE instead of `./config.cache`. Set FILE to `/dev/null` to disable caching, for debugging `configure`.

`--help`

Print a summary of the options to `configure`, and exit.

`--quiet`

`--silent`

`-q`

Do not print messages saying which checks are being made. To suppress all normal output, redirect it to `/dev/null` (any error messages will still be shown).

`--srcdir=DIR`

Look for the package's source code in directory DIR. Usually

`configure' can determine that directory automatically.

`--version'

Print the version of Autoconf used to generate the `configure' script, and exit.

`configure' also accepts some other, not widely useful, options.

File = INSTALL.~1~

DBus Installation =====

Quick start =====

DBus could be build with GNU AutoTools or with cmake for its build system, thus the basic install procedure can be summarized as:

with autotools:

```
./configure --prefix=/usr
make
su make install
```

The configure script will automatically determine whether to try and build bindings for GLib, Qt, Qt3, Python and Mono based on what tools are installed on the host system. The default build behaviour can be overridden using the --enable-XXX/--disable-XXX arguments to configure.

A typical scenario in which it is desirable to override automatic detection, is during packaging of binary builds, where a predictable dependancy chain is required. For more details on GNU AutoTools installation, consult the generic instructions later in this document

with cmake:

```
mkdir dbus-build-dir
cd dbus-build-dir
cmake -G <makefile-generator-name> [-D<option>] <dbus-src-root>/cmake
make
make install
```

cmake will automatically determine whether to build some features based on what tools and/or libraries are installed on the host system. The default build behaviour can be overridden using the -DENABLE_<XXX> arguments to cmake.

A typical scenario in which it is desirable to override automatic detection, is during packaging of binary builds, where a predictable

dependency chain is required. For more details on cmake installation, consult <http://www.cmake.org/cmake/help/help.html>.

External software dependancies =====

The only fundamental requirement to build DBus is an XML parser, however, there are a number of other software packages which (if present) will enhance functionality.

Core library -----

Requisite:

- Gettext
- expat or libxml-2

NB, expat is the recommended XML parser because it has more robust handling of OOM conditions.

Optional:

- libselinux (for SELinux integration)
- dnotify (for automatic service file reload)
- doxygen (for API documentation)
- xmlto or meinproc4 (for Spec & other XML documentation)

=====

The rest of this document contains the generic GNU AutoTools install instructions....

Basic Installation =====

These are generic installation instructions.

The ``configure'` shell script attempts to guess correct values for various system-dependent variables used during compilation. It uses those values to create a ``Makefile'` in each directory of the package. It may also create one or more ``.h'` files containing system-dependent definitions. Finally, it creates a shell script ``config.status'` that you can run in the future to recreate the current configuration, a file ``config.cache'` that saves the results of its tests to speed up reconfiguring, and a file ``config.log'` containing compiler output (useful mainly for debugging ``configure'`).

If you need to do unusual things to compile the package, please try to figure out how ``configure'` could check whether to do them, and mail diffs or instructions to the address given in the ``README'` so they can

be considered for the next release. If at some point `config.cache` contains results you don't want to keep, you may remove or edit it.

The file `configure.in` is used to create `configure` by a program called `autoconf`. You only need `configure.in` if you want to change it or regenerate `configure` using a newer version of `autoconf`.

The simplest way to compile this package is:

1. `cd` to the directory containing the package's source code and type
`./configure` to configure the package for your system. If you're using `csh` on an old version of System V, you might need to type `sh ./configure` instead to prevent `csh` from trying to execute `configure` itself.

Running `configure` takes awhile. While running, it prints some messages telling which features it is checking for.

2. Type `make` to compile the package.
3. Optionally, type `make check` to run any self-tests that come with the package.
4. Type `make install` to install the programs and any data files and documentation.
5. You can remove the program binaries and object files from the source code directory by typing `make clean`. To also remove the files that `configure` created (so you can compile the package for a different kind of computer), type `make distclean`. There is also a `make maintainer-clean` target, but that is intended mainly for the package's developers. If you use it, you may have to get all sorts of other programs in order to regenerate files that came with the distribution.

Compilers and Options =====

Some systems require unusual options for compilation or linking that the `configure` script does not know about. You can give `configure` initial values for variables by setting them in the environment. Using a Bourne-compatible shell, you can do that on the command line like this:

```
CC=c89 CFLAGS=-O2 LIBS=-lposix ./configure
```

Or on systems that have the ``env'` program, you can do it like this:
`env CPPFLAGS=-I/usr/local/include LDFLAGS=-s ./configure`

Compiling For Multiple Architectures

```
=====
```

You can compile the package for more than one kind of computer at the same time, by placing the object files for each architecture in their own directory. To do this, you must use a version of ``make'` that supports the ``VPATH'` variable, such as GNU ``make'`. ``cd'` to the directory where you want the object files and executables to go and run the ``configure'` script. ``configure'` automatically checks for the source code in the directory that ``configure'` is in and in ``..'`.`

If you have to use a ``make'` that does not support the ``VPATH'` variable, you have to compile the package for one architecture at a time in the source code directory. After you have installed the package for one architecture, use ``make distclean'` before reconfiguring for another architecture.

Installation Names

```
=====
```

By default, ``make install'` will install the package's files in ``/usr/local/bin'`, ``/usr/local/man'`, etc. You can specify an installation prefix other than ``/usr/local'` by giving ``configure'` the option ``--prefix=PATH'`.

You can specify separate installation prefixes for architecture-specific files and architecture-independent files. If you give ``configure'` the option ``--exec-prefix=PATH'`, the package will use `PATH` as the prefix for installing programs and libraries. Documentation and other data files will still use the regular prefix.

In addition, if you use an unusual directory layout you can give options like ``--bindir=PATH'` to specify different values for particular kinds of files. Run ``configure --help'` for a list of the directories you can set and what kinds of files go in them.

If the package supports it, you can cause programs to be installed with an extra prefix or suffix on their names by giving ``configure'` the option ``--program-prefix=PREFIX'` or ``--program-suffix=SUFFIX'`.

Optional Features

=====

Some packages pay attention to `--enable-FEATURE` options to `configure`, where `FEATURE` indicates an optional part of the package. They may also pay attention to `--with-PACKAGE` options, where `PACKAGE` is something like `gnu-as` or `x` (for the X Window System). The `README` should mention any `--enable-` and `--with-` options that the package recognizes.

For packages that use the X Window System, `configure` can usually find the X include and library files automatically, but if it doesn't, you can use the `configure` options `--x-includes=DIR` and `--x-libraries=DIR` to specify their locations.

Specifying the System Type

=====

There may be some features `configure` can not figure out automatically, but needs to determine by the type of host the package will run on. Usually `configure` can figure that out, but if it prints

a message saying it can not guess the host type, give it the `--host=TYPE` option. `TYPE` can either be a short name for the system type, such as `sun4`, or a canonical name with three fields:
CPU-COMPANY-SYSTEM

See the file `config.sub` for the possible values of each field. If `config.sub` isn't included in this package, then this package doesn't need to know the host type.

If you are building compiler tools for cross-compiling, you can also use the `--target=TYPE` option to select the type of system they will produce code for and the `--build=TYPE` option to select the type of system on which you are compiling the package.

Sharing Defaults

=====

If you want to set default values for `configure` scripts to share, you can create a site shell script called `config.site` that gives default values for variables like `CC`, `cache_file`, and `prefix`. `configure` looks for `PREFIX/share/config.site` if it exists, then `PREFIX/etc/config.site` if it exists. Or, you can set the `CONFIG_SITE` environment variable to the location of the site script. A warning: not all `configure` scripts look for a site script.

Operation Controls

=====

`configure' recognizes the following options to control how it operates.

`--cache-file=FILE'

Use and save the results of the tests in FILE instead of `./config.cache'. Set FILE to `/dev/null' to disable caching, for debugging `configure'.

`--help'

Print a summary of the options to `configure', and exit.

`--quiet'

`--silent'

`-q'

Do not print messages saying which checks are being made. To suppress all normal output, redirect it to `/dev/null' (any error messages will still be shown).

`--srcdir=DIR'

Look for the package's source code in directory DIR. Usually `configure' can determine that directory automatically.

`--version'

Print the version of Autoconf used to generate the `configure' script, and exit.

`configure' also accepts some other, not widely useful, options.
